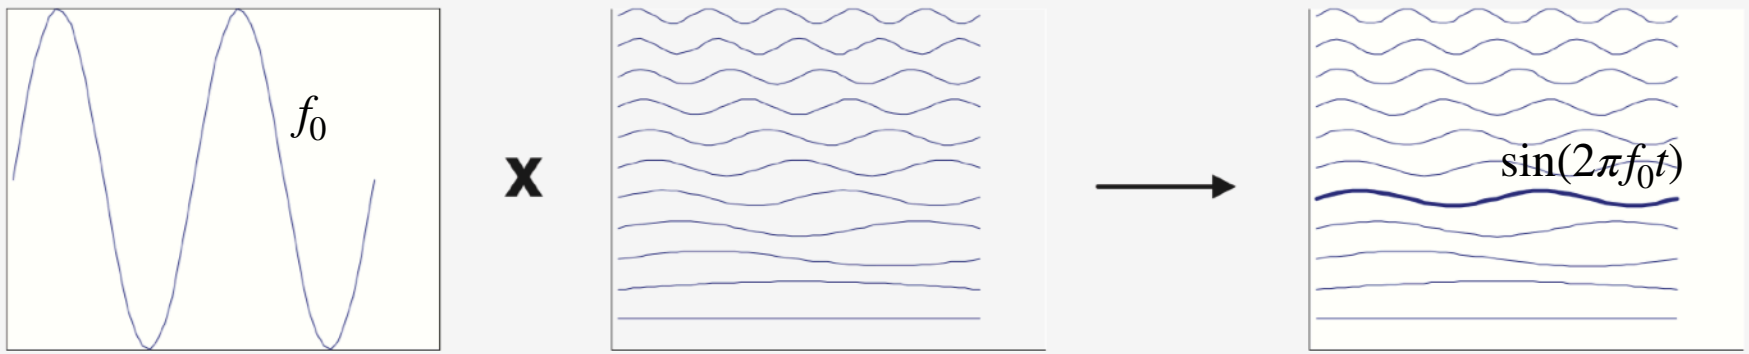
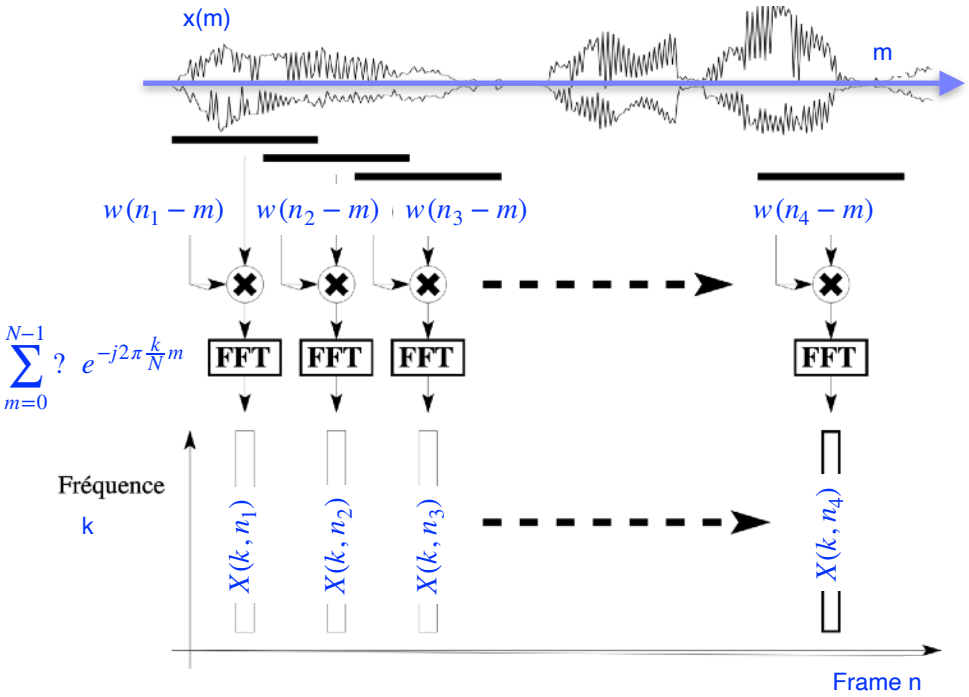
Fourier Transform
continuous time and frequency

- $$X(\omega) = \int_t x(t) e^{-j\omega t} dt \quad X(f) = \int_t x(t) e^{-j(2\pi f)t} dt$$
  - Variables
    - t : time
    - $\omega = 2\pi f$: continuous frequency in radian
    - $\exp(j2\pi ft) = \cos(2\pi ft) + j\sin(2\pi ft)$
  - Why the Fourier Transform ?
    - It is difficult to interpret directly the value of the waveform $x(t)$
    - Reproduce the frequency decomposition of human earing



Fourier Transform short time (STFT)

- $$X(k,n) = \sum_{m=-\infty}^{+\infty} \underline{w(n-m)}\, x(m)\, e^{-j2\pi\frac{k}{N}m} \quad \forall k \in [0, N-1]$$
  - Apply the DFT on successive segments of the audio signal,
    - each segment is centred/start around time n
  - Why the STFT ?
    - Audio signal= non-stationary
      - its properties evolve over time
    - "Local" (in time) stationarity
      - over a time duration of $\pm 40\ ms$
    - STFT: a set of successive DFT over segments of $\pm 40\ ms$ duration
      - = Short-time analysis ("frames" in video)



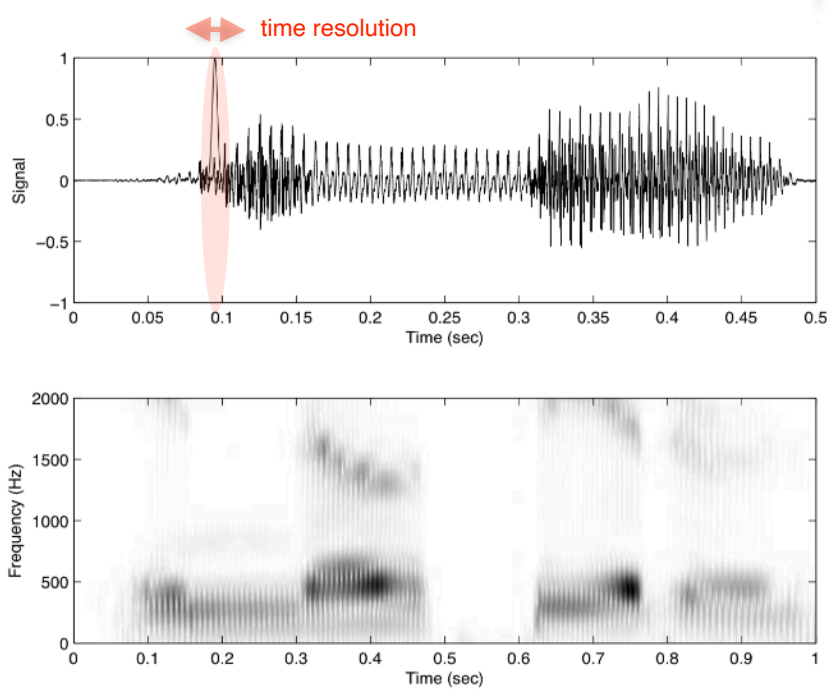
Fourier Transform short time (STFT)

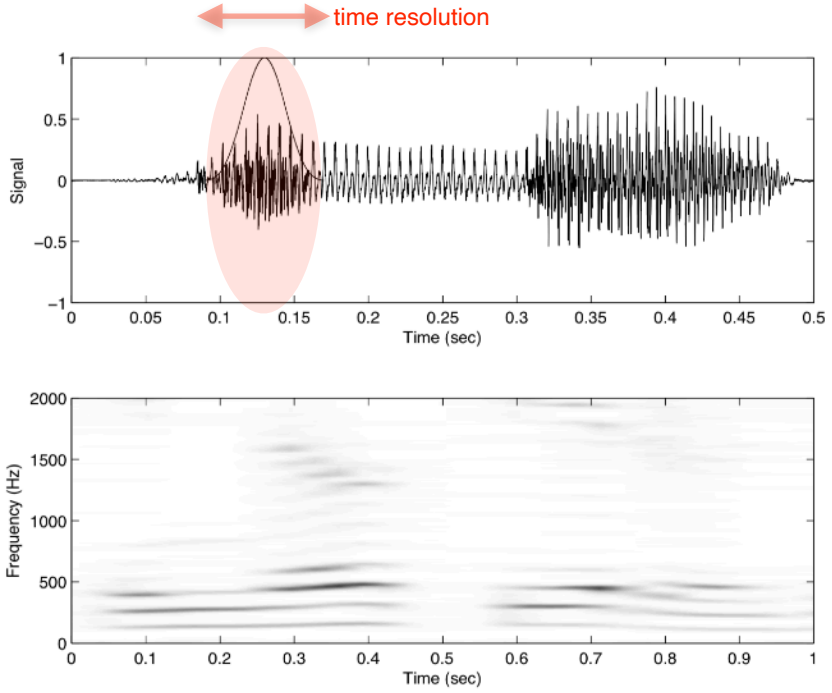
- $$X(k,n) = \sum_{m=-\infty}^{+\infty} \underline{w(n-m)}\, x(m)\, e^{-j2\pi \frac{k}{N} m} \quad \forall k \in [0, N-1]$$
  - Analysis window $w(t)$
  - $x(t) \cdot w(t) \rightleftarrows X(f) \circledast W(f)$
    - $w(t)$ is named "analysis window"
    - Parameters:
      - 1) **type** of the analysis window $w(t)$
      - 2) **time duration** L of the window $w(t)$
    - The type and time duration defines the spectral characteristics of the STFT
      - Width of the main lobe (at $-6dB_{20}$): $Bw = \frac{Cw}{L}$
      - Height of secondary lobes

Propriétés	$x(t)$	$X(f)$
Similitude	$x(at)$	$\frac{1}{\lvert a \rvert} X(\frac{f}{a})$
Linéarité	$ax(t) + by(t)$	$aX(f) + bY(f)$
Translation	$x(t - t_0)$	$X(f) \exp(-j2\pi f t_0)$
Modulation	$x(t) \exp(j2\pi f_0 t)$	$X(f - f0)$
Convolution	$x(t) \circledast y(t)$	$X(f)Y(f)$
Produit	$x(t)y(t)$	$X(f) \circledast Y(f)$
Parité	réelle paire	réelle paire
	réelle impaire	imaginaire paire
	imaginaire paire	imaginaire paire
	imaginaire impaire	réelle impaire
	complexe paire	complexe paire
	complexe impaire	complexe impaire
	réelle	$X(f) = X^*(-f)$
		$\Re(X(f))$ est paire
		$\Im(X(f))$ est impaire
	$x^*(t)$	$X^*(f)$

Fourier Transform short time (STFT)

- **Time and frequency paradox**
  - It is not possible to observe the signal with a good time and frequency localisation simultaneously !

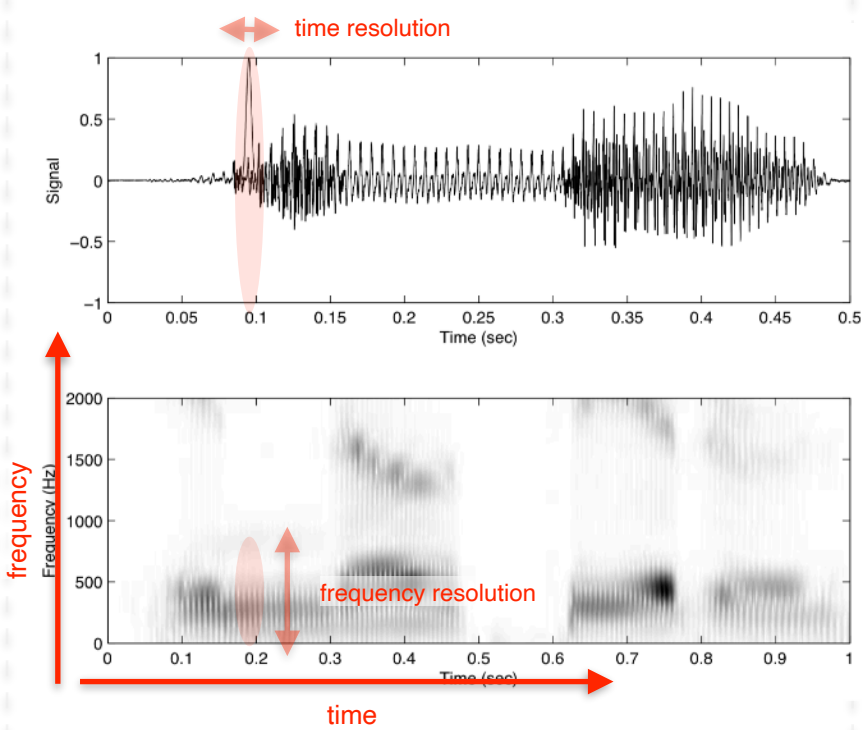


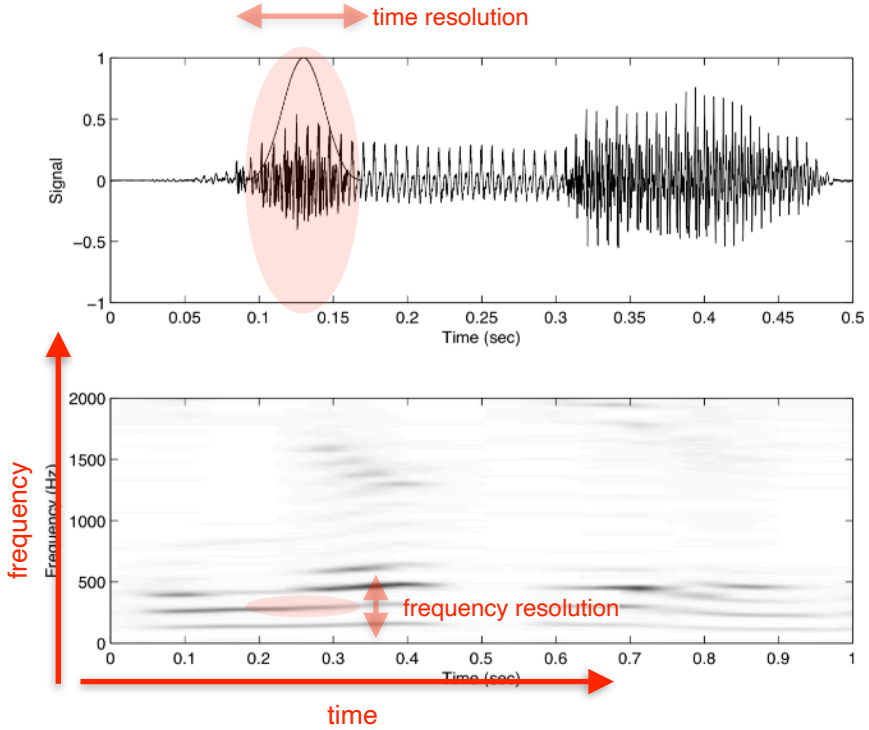


- **How to solve this issue ?**
  - Other transforms: wavelet, constant-Q-transform

Fourier Transform short time (STFT)

- **Time and frequency paradox**
  - It is not possible to observe the signal with a good time and frequency localisation simultaneously !





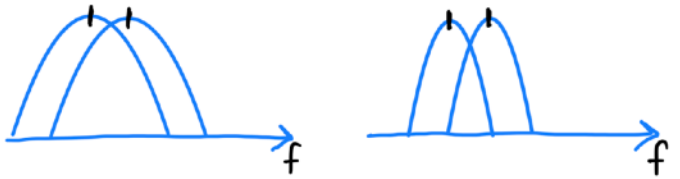
- **How to solve this issue ?**
  - Other transforms: wavelet, constant-Q-transform

Constant-Q-Transform (CQT)

- Discrete Fourier Transform (DFT)
  - _ Definition : Spectral **precision** : $\Delta f = \frac{sr}{N}$
    - it is the step-size at which the Fourier spectrum is sampled
    - it depends on the size of the DFT: N
    - we can improve the precision by increasing N

  - _ Definition : Spectral **resolution** : $B_w = \frac{C_w}{L}$
    - it describes the ability to discriminate (separate in the spectrum) two adjacent simultaneous frequencies

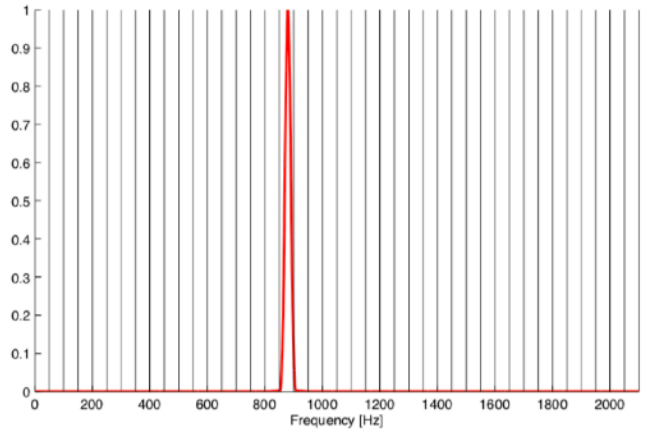
  - – Warning :
    - even if we increase N (zero-padding) while keeping L constant will not improve the resolution !



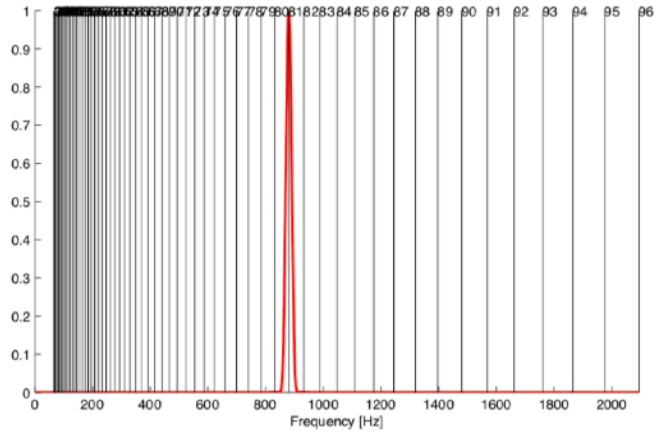
- In a DFT:
  - – Spectral precision and resolution are constant over frequencies

Constant-Q-Transform (CQT)

- In musical audio
  - the frequencies of the pitches are logarithmically spaced $f_k = f_0 \cdot 2^{\frac{k}{12}}$
    - if we choose A-4 = la-3 = 440 Hz as the reference
    - to go from midi-pitches m_k to frequencies f_k:
      - $f_k = 440 \cdot 2^{\frac{m_k - 69}{12}}$
    - to go from frequencies f_k to midi-pitches m_k:
      - $m_k = 12 \log_2 \frac{f_k}{440} + 69$
  - pitch frequencies are
    - close together in low frequencies,
    - distant in high frequencies
  - The **spectral resolution** of the DFT
    - is not sufficient (to separate adjacent notes) in low frequencies
    - is too large for high frequencies



Espacement linéaire de la DFT



Espacement logarithmique des hauteurs de notes

Constant-Q-Transform (CQT)

- Solution ?
  - Change the spectral resolution B_w depending on the frequency f_k being considered

- How ?
  - By changing the window length L for eadh frequency f_k
  - The factor $Q = \frac{f_k}{f_{k+1} - f_k}$ should remains constant in frequency
    - $Q = \frac{f_k}{Bw} = \frac{f_k}{Cw/L} = \frac{f_k \cdot L}{Cw}$
  - We choose a different L for each frequency f_k
    - $L_k = \frac{Q \cdot Cw}{f_k}$

An efficient algorithm for the calculation of a constant Q transform

Judith C. Brown

Physics Department, Wellesley College, Wellesley, Massachusetts 02181 and Media Laboratory, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Miller S. Puckette

IRCAM, 31 rue St Merri, Paris 75004, France

(Received 5 February 1992; revised 10 April 1992; accepted 16 June 1992)

An efficient method of transforming a discrete Fourier transform (DFT) into a constant Q transform, where Q is the ratio of center frequency to bandwidth, has been divided. This method involves the calculation of kernels that are then applied to each subsequent DFT. Only a few multiplies are involved in the calculation of each component of the constant Q transform, so this transformation adds a small amount to the computation. In effect, this method makes it possible to take full advantage of the computational efficiency of the fast Fourier transform (FFT). Graphical examples of the application of this calculation to musical signals are given for sounds produced by a clarinet and a violin.

Traditional machine-learning approach

Traditional approach

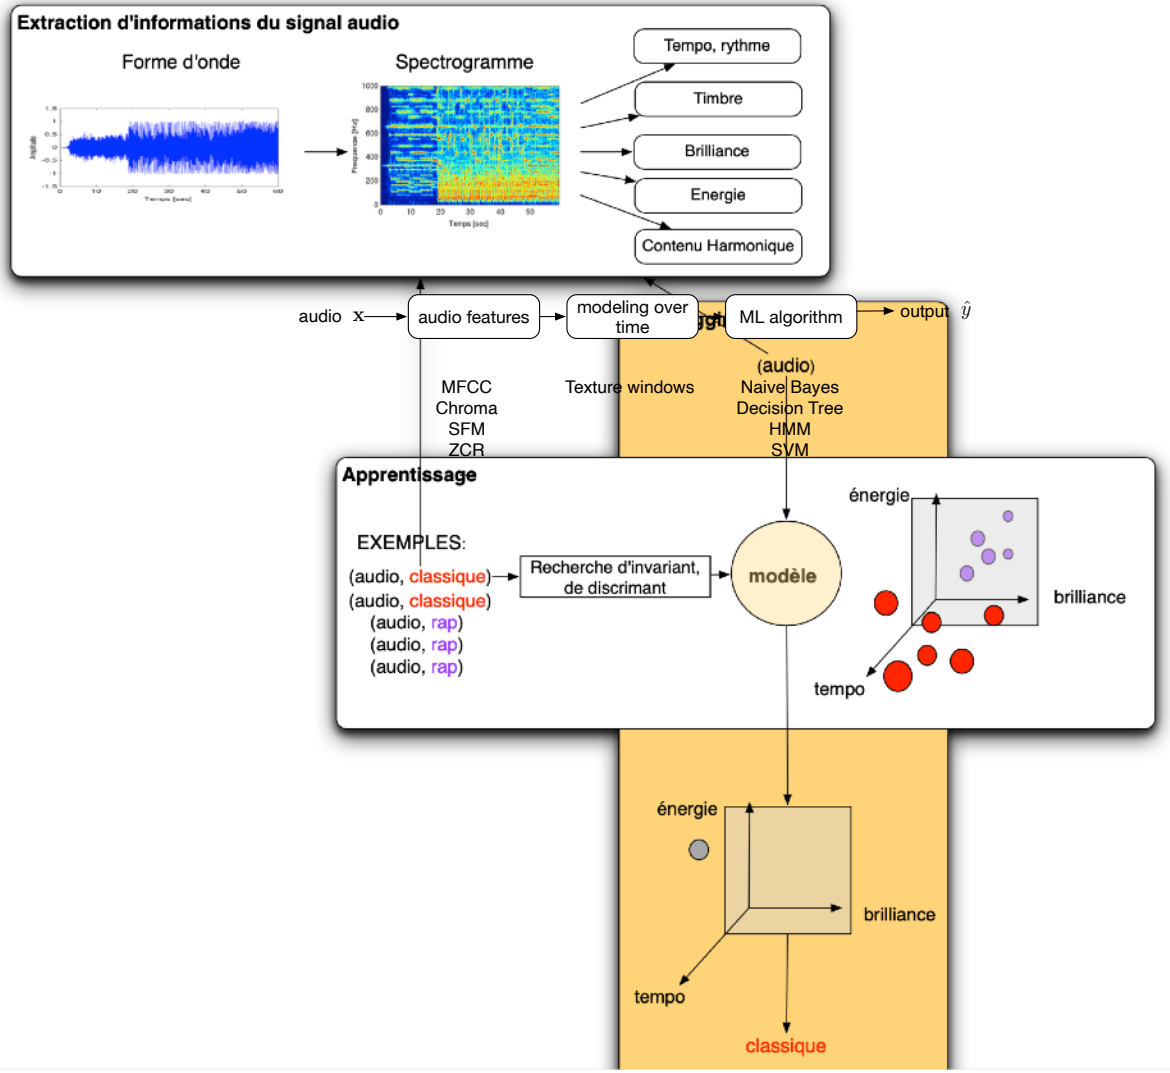
- Training phase
- **Testing phase**



Audio features

Audio features examples

Zero-crossing rate (zcr)

- Measures the number of times the audio waveform cross the zero-axis
  - $$zcr = \frac{1}{N}\sum_{n=1}^{N} |sign(x_n) - sign(x_{n-1})|$$
- Usage: allows to distinguish
  - harmonic sounds → low zcr
  - noise sounds→ high zcr

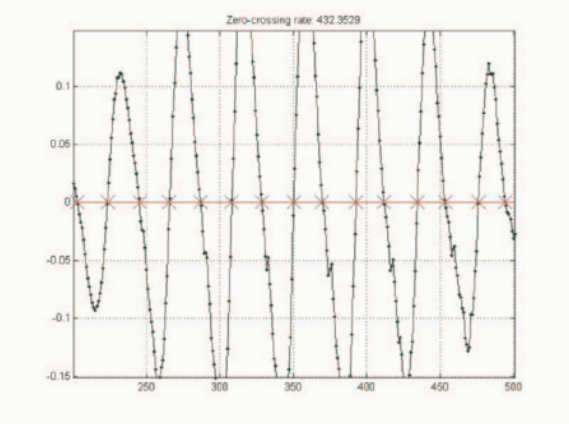


Figure 12 Zero-crossing rate (=432) during voiced speech region

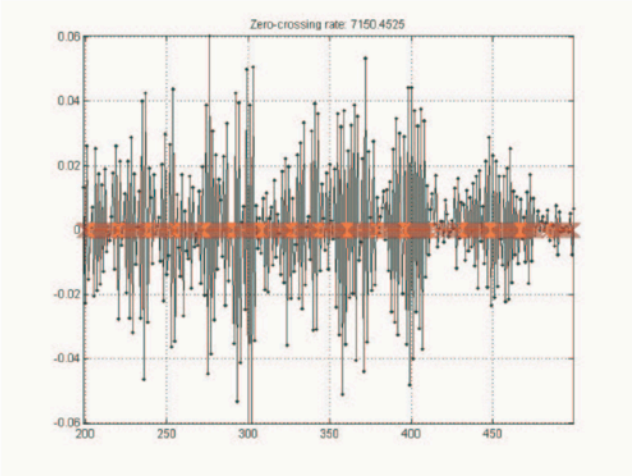

Figure 13 Zero-crossing rate (=7150) during unvoiced speech region

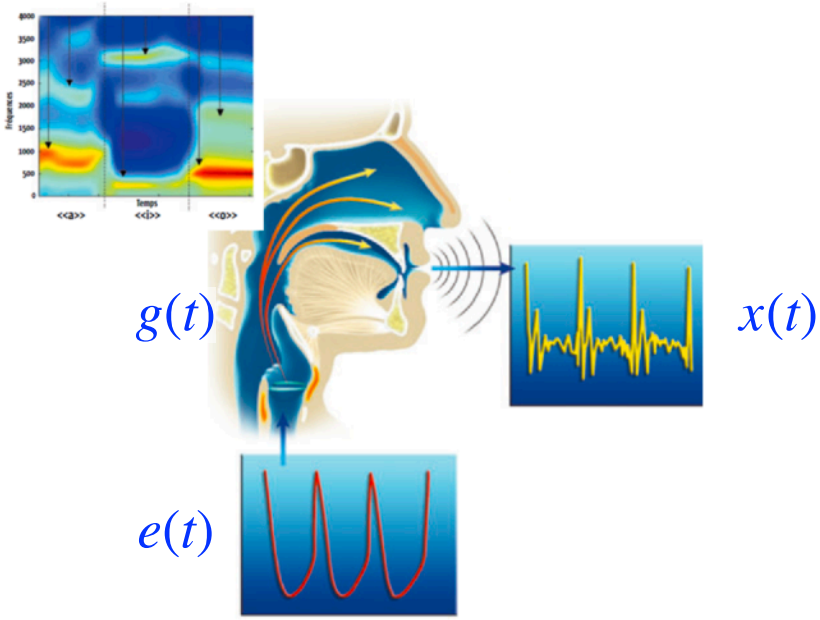
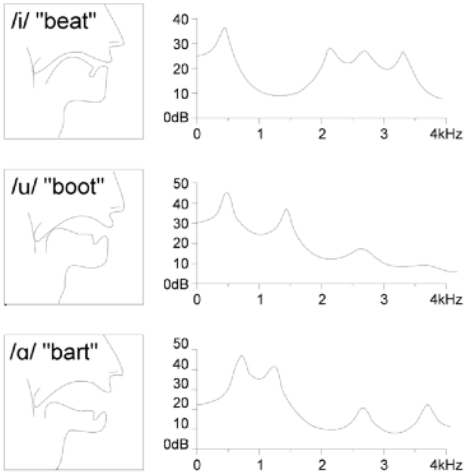
Source/Filter model

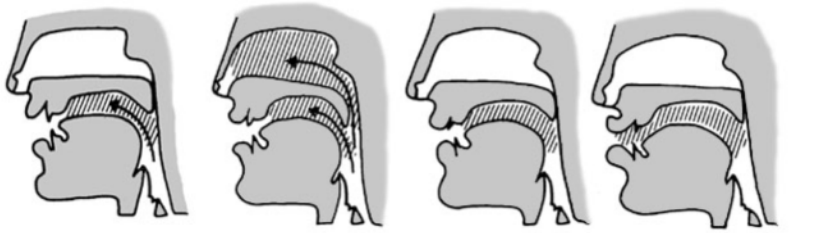
Model:

- represent the signal $x(t)$ as the results of a periodic pulse signal convolved with a resonant filters
- Example:
  - speech (voiced part)
    - vocal folds $e(t)$
    - mouth (resonance), nose (anti-resonance) $g(t)$
  - many musical instruments (trumpet)





source : Mike Brookes



source : outilsrecherche.over-blog.com

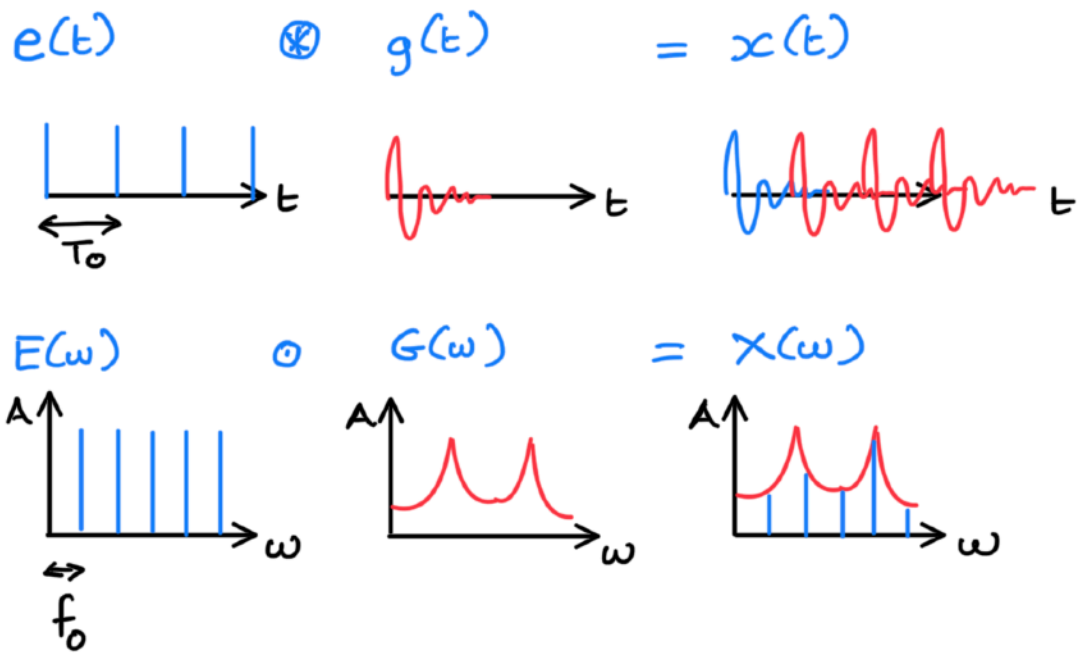
Source/Filter model

In time:

$$x(t) = e(t) \circledast g(t)$$

In frequency:

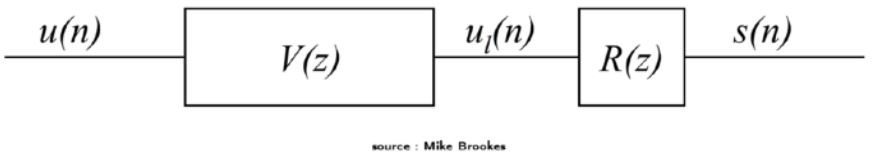
$$X(\omega) = E(\omega) \cdot G(\omega)$$



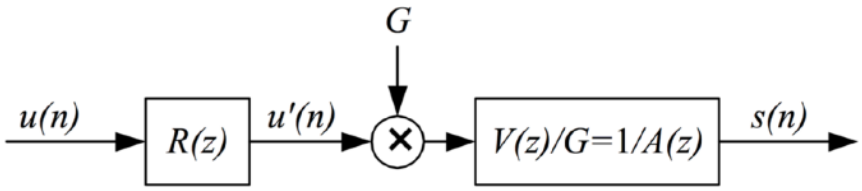
Source/Filter model

Resonant filter:

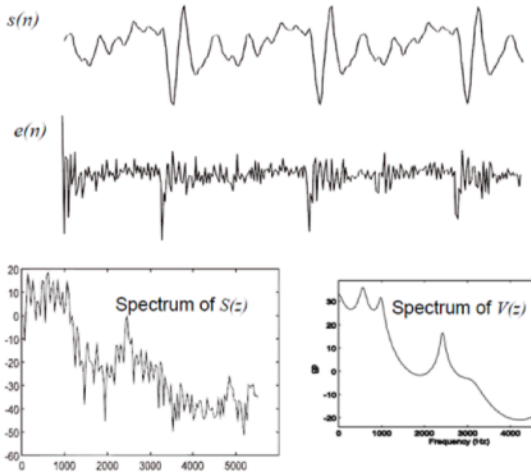
- $V(z) = \dfrac{G}{1 - \sum_{j=1}^{P} a_j z^{-j}}$
  - $x(n) = Gu'(n) + \sum_{j=1}^{P} a_j x(n-j)$
- If the gain of the resonances of the vocal fold are import, the second term dominates and
  - $x(n) \simeq \sum_{j=1}^{P} a_j x(n-j)$
  - This is an **auto-regressive model**



source : Mike Brookes



source : Mike Brookes



Audio features examples
Mel Frequency Cepstral Coefficients (1)

Complex cepstrum

– **Goal**

- describe the shape of the spectrum (the timbre) of a signal using a reduced set of coefficients

– **Complex cepstrum** $c(\tau)$

$$c(\tau) = TF^{-1}\left[\log(X(\omega))\right]$$
$$= \frac{1}{2\pi}\int_{\omega} \log[X(\omega)] \cdot e^{j\omega\tau} d\omega$$

- τ is named "**quefrency**" (=frequency in reverse order)
- $x(t) \xrightarrow{TF} X(\omega) \xrightarrow{\log} \log(X(\omega)) \xrightarrow{TF^{-1}} c(\tau)$

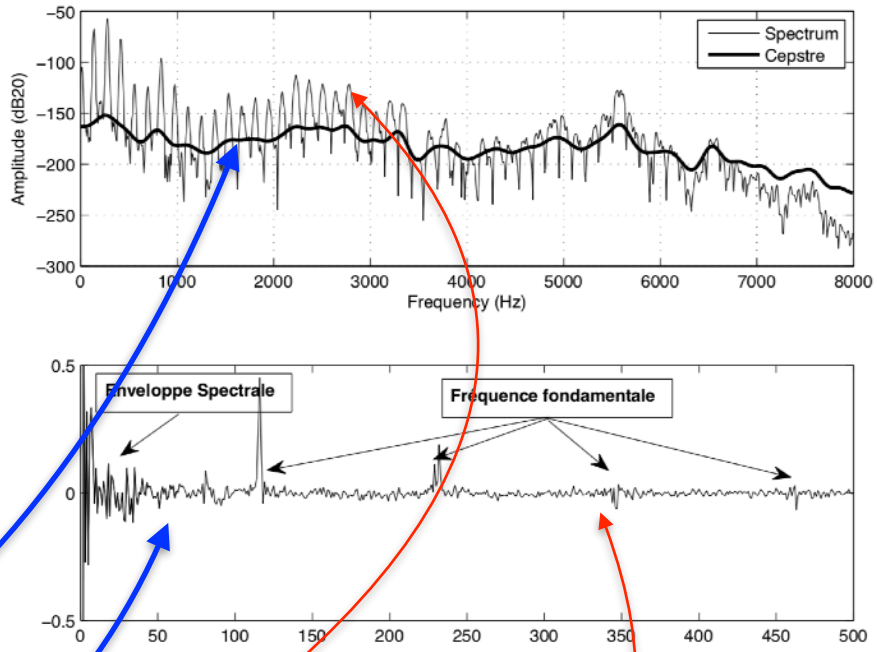
Audio features examples
Mel Frequency Cepstral Coefficients (2)

Source/filter model

- Source $e(t)$: periodic signal
- Filter $g(t)$: resonant/ anti-resonant filter

$$x(t) = e(t) \circledast g(t)$$

$$\xrightarrow{TF} X(\omega) = E(\omega) \cdot G(\omega)$$



$$\xrightarrow{\log} \log(X(\omega)) = \underbrace{\log[G(\omega)]}_{\text{slow variations over } \omega} + \underbrace{\log[E(\omega)]}_{\text{fast variations over } \omega}$$

$$\xrightarrow{TF^{-1}} TF^{-1}\left[\log(X(\omega))\right] = \underbrace{TF^{-1}\left[\log[G(\omega)]\right]}_{\text{energy at quefrency } \tau<<} + \underbrace{TF^{-1}\left[\log[E(\omega)]\right]}_{\text{energy at quefrency } \tau>>}$$

Audio features examples
Mel Frequency Cepstral Coefficients (4)

Mel Frequency Cepstral Coefficients (MFCCs)

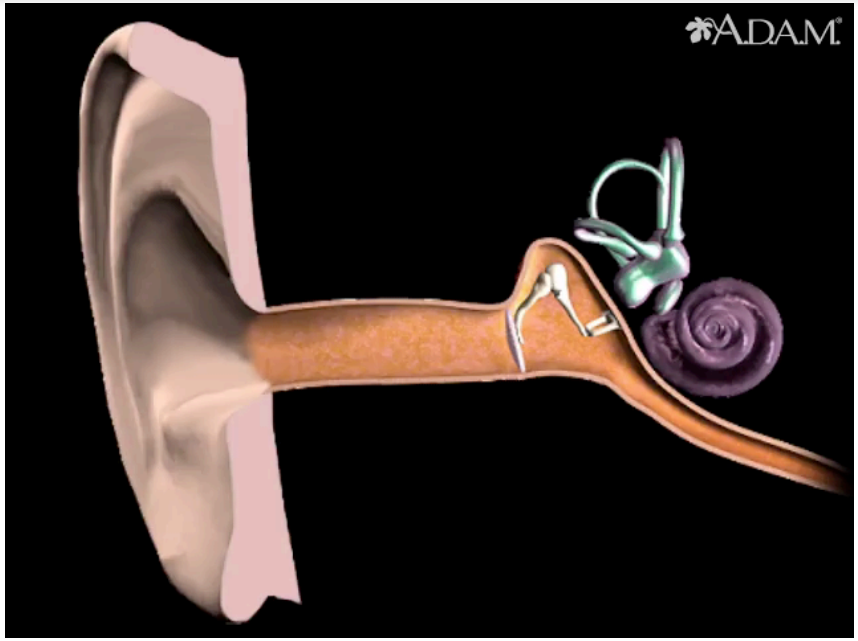
- MFCC ? = real cepstrum computed on the power spectrum $|X(\omega)|^2$ converted to the Mel scale (a perceptual scale)

- **Why perceptual scales ?**
  - Fourier Transform
    - decomposition on a set of sinusoidal components which frequencies are linearly spaced (f_k = 10Hz, 20Hz, 30Hz, ... Hz)
  - Human hearing:
    - decomposition on a set of filters which frequencies are logarithmically spaced (10, 20, 40, 80, ... Hz).
    - highest resolution in low-frequencies, lowest resolution in high frequencies
    - in speech, formants/resonances are closer together in low frequencies
  - MFCCs allows a more compact representation than the real cepstrum
- **How ?**
  - Use of perceptual scales: Mel-scale, Bark-scale, ERB-filters, Gamma-tone filters
- **Usage ?**
  - MFCCs are the most used features in audio: speech, music, environmental sounds recognition, ...

Audio features examples
Mel Frequency Cepstral Coefficients (5)

Human hearing

- Cochlea



https://medlineplus.gov/ency/anatomyvideos/000063.htm

- Critical bands
  - perception of two tones at f_1 and f_2
  - perception of a beating-tone at $\frac{f_1+f_2}{2}$

$$\cos f_1 + \cos f_2 = 2\cos\frac{f_1-f_2}{2}\cos\frac{f_1+f_2}{2}$$

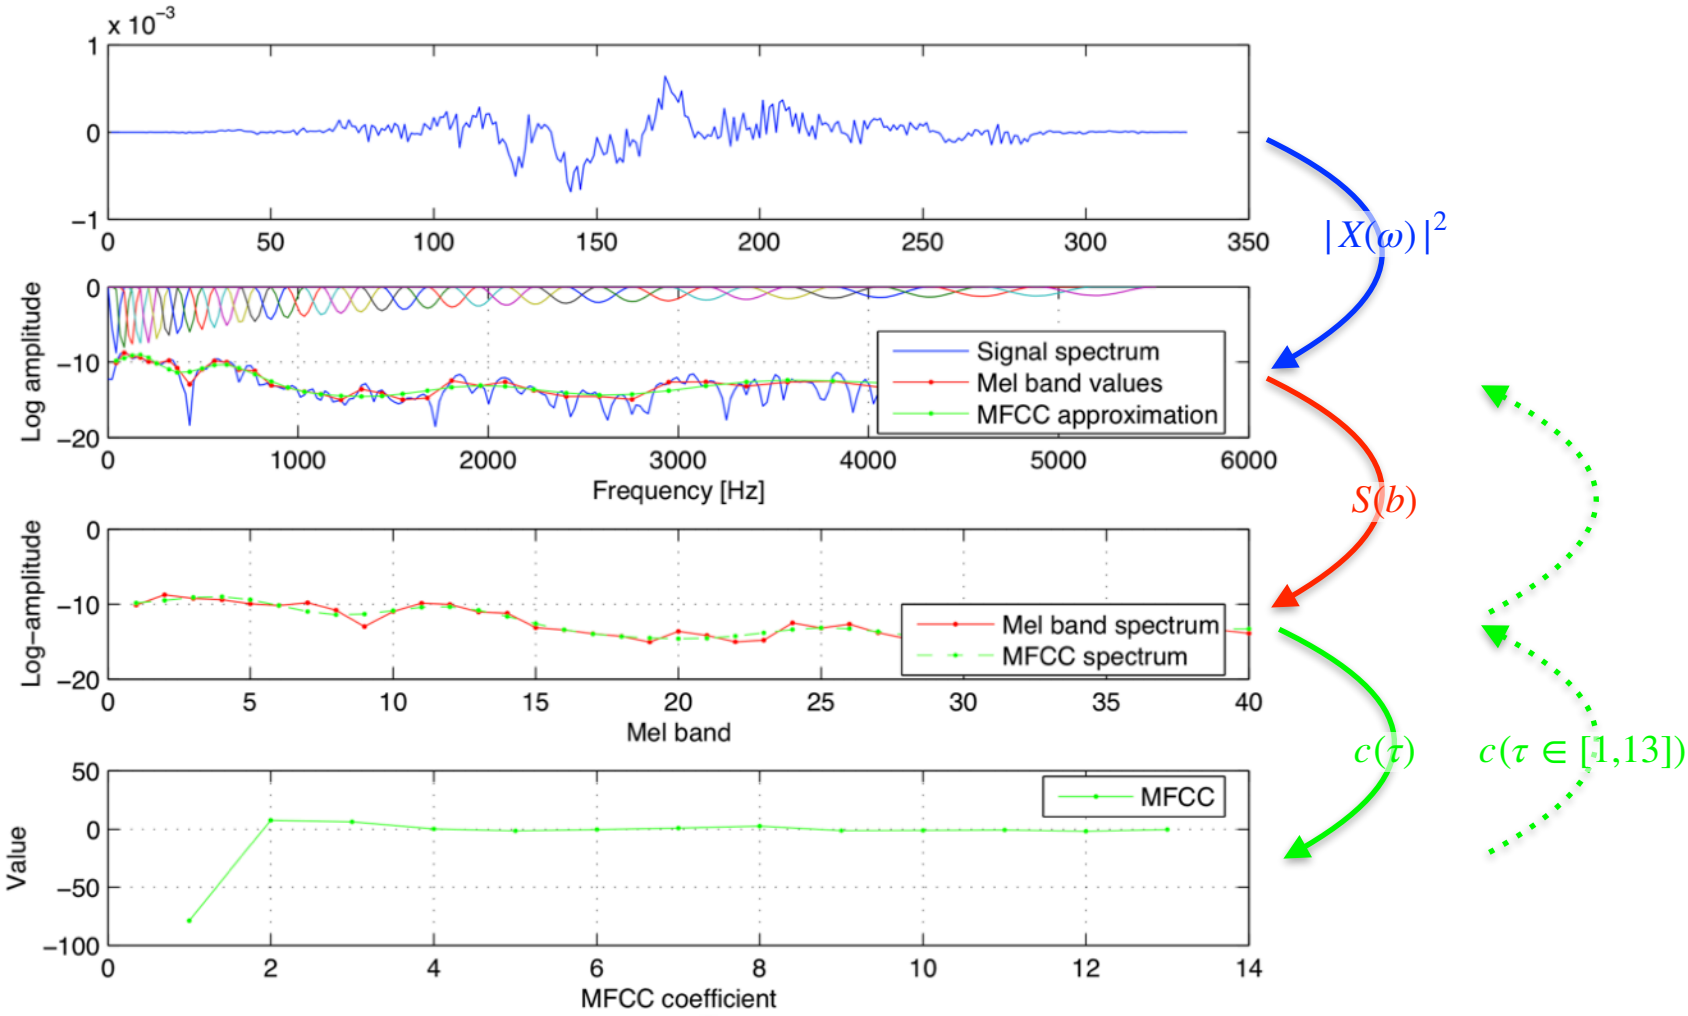
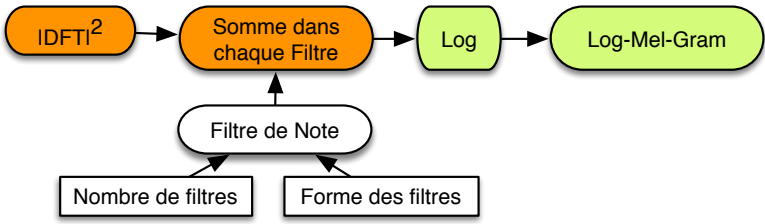
Example of the computation of MFCCs

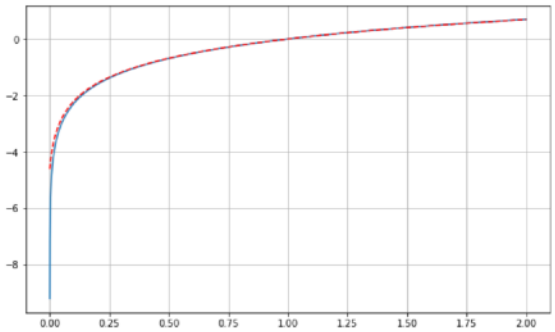


Audio features examples
Mel Frequency Cepstral Coefficients (9)

Variation for the case of DNN inputs: the Log-Mel-gram

- In the **Cepstrum**
  - the DCT is used to separate the contribution of the source and the filter
- In the **Mel Frequency Cepstral Coefficients**
  - the Mel-bands already mostly represent the filter contribution
  - the DCT is mostly used to de-correlated the dimensions
    - (latter used in GMM:diagonal covariance matrix Σ)
- **Log-Mel-Gram**
  - When using DNN, we don't need such a de-correlation of the inputs
  - we then bypass the DCT of the MFCC → Log-Mel-Gram
  - Tricks: to avoid singularity of $\log(x)$ → replace log by $\log(1+\gamma x)$ with $\gamma = 100$





Sinusoidal (harmonic) model

Model:

- represent the signal $x(t)$ as a sum of (harmonic) sinusoidal components + noise

$$x(t) = \sum_{h=1}^{H(t)} A_h(t) \cdot \cos(\phi_h(t)) + b(t)$$

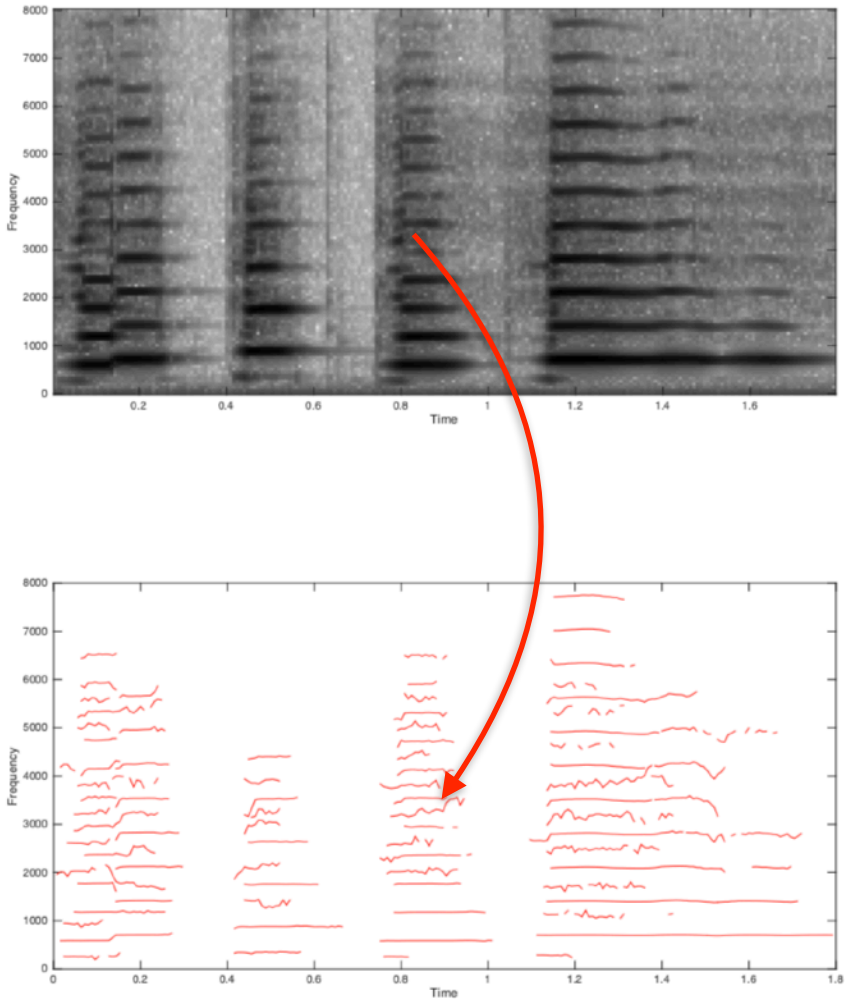
- Fourier series
- Organ musical instrument

Hypothesis:

- Number of components $H(t)$ is reduced ($\neq$ Fourier Transform)
- Parameters slowly vary over time
  - local stationarity
  - we can approximate locally in time
    - $A_h(t) = A_h(t_m)$
    - $\phi(t) = 2\pi f_h(t_m)(t - t_m) + \phi_h(t_m)$

$$\hat{x}_m(t_m) = \sum_{h=1}^{H(t)} A_h(t_m) \cdot \cos\left(2\pi f_h(t_m)(t - t_m) + \phi_h(t_m)\right)$$

$$\hat{x}(t) = \sum_{m} \hat{x}_m(t) + b(t)$$

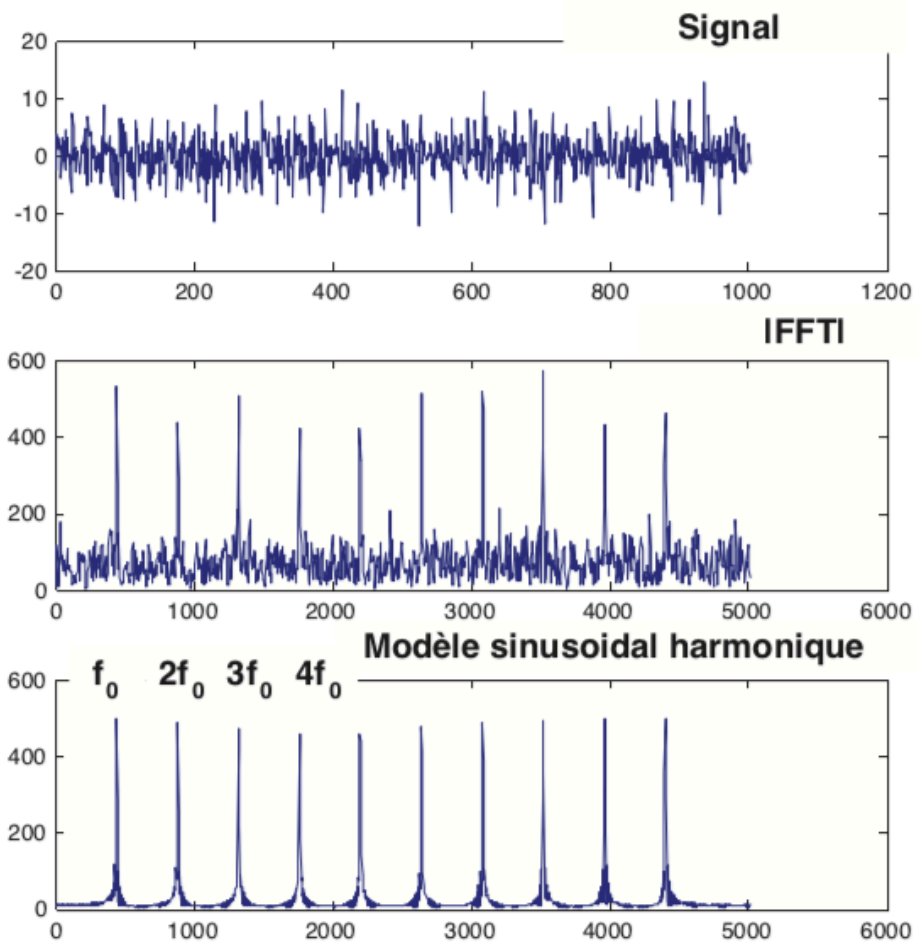


[X. Serra and J. Smith. "**Spectral modeling synthesis: A sound analysis/synthesis system** ..." In CMJ, 1990] LINK

Sinusoidal (harmonic) model

Hypothesis:

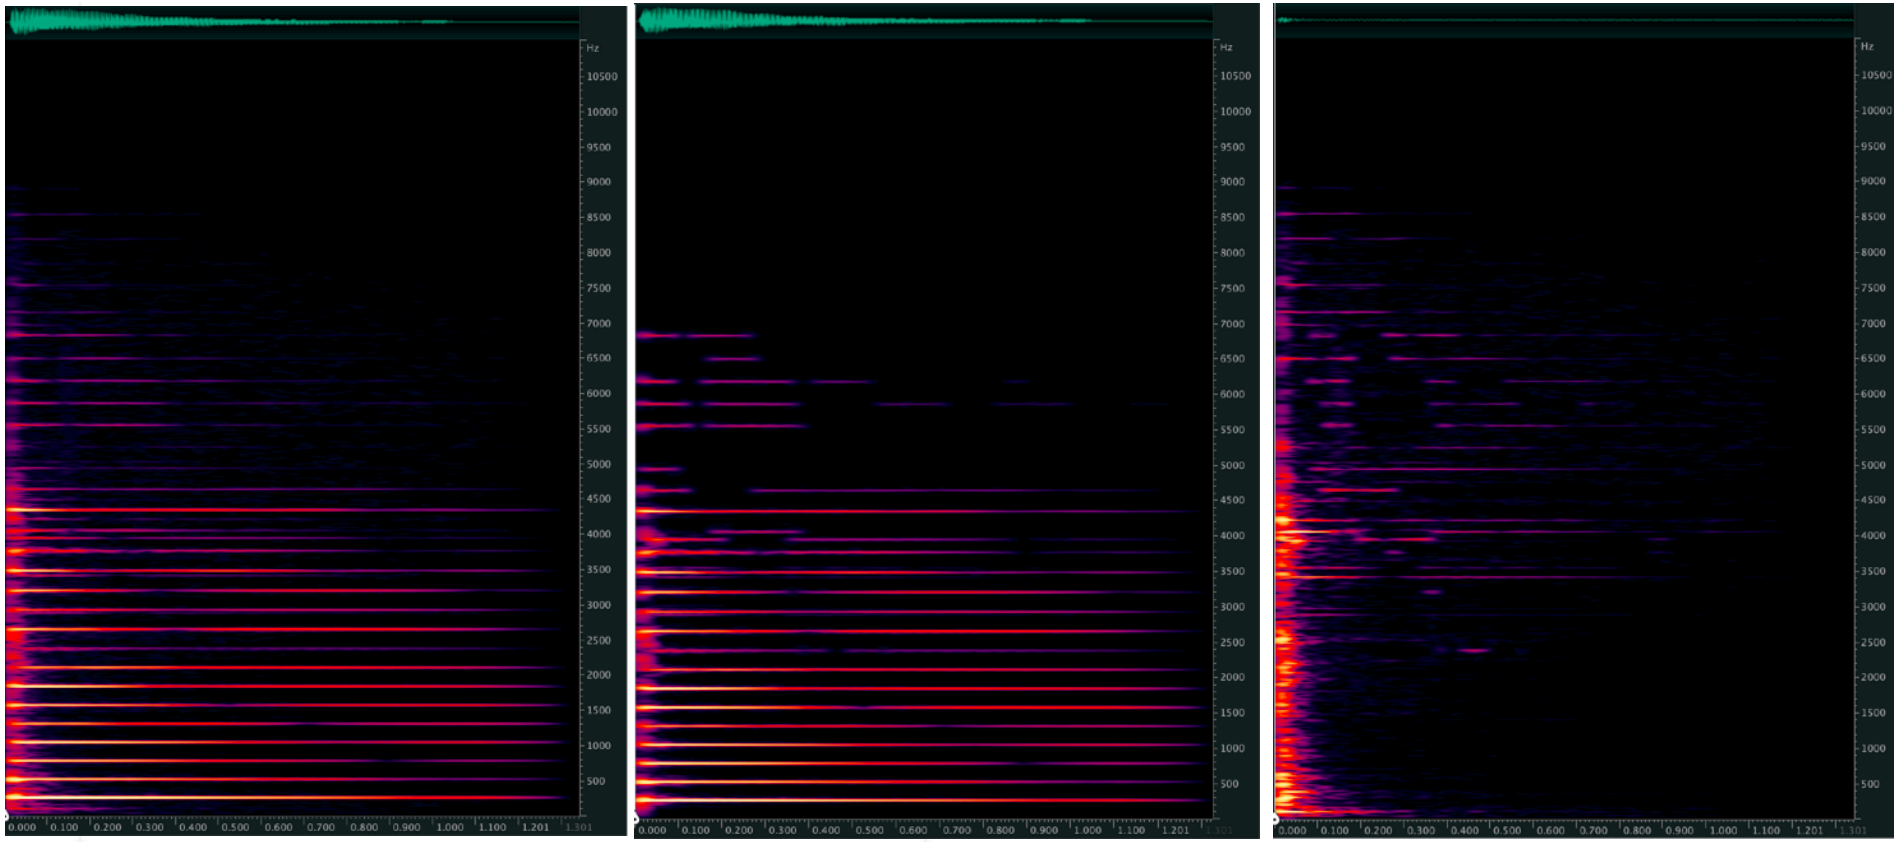
- $x(t)$ is a single source, mono-phonic, harmonic sound
- exemple: voiced speech, musical instruments
- $f_h(t_m) = hf_0(t_m)$
  - If we know $f_0(t_m)$ (pitch tracking), we can deduce the frequencies of the sinusoidal components: $f_h(t_m) = hf_0(t_m)$,
  - We only need to estimate the amplitude and initial phases: $A_h(t_m)$ et le $\phi_h(t_m)$
  - $H(t)$ is constant over time
  - No needs for partial tracking



Sinusoidal (harmonic) model

Examples: piano

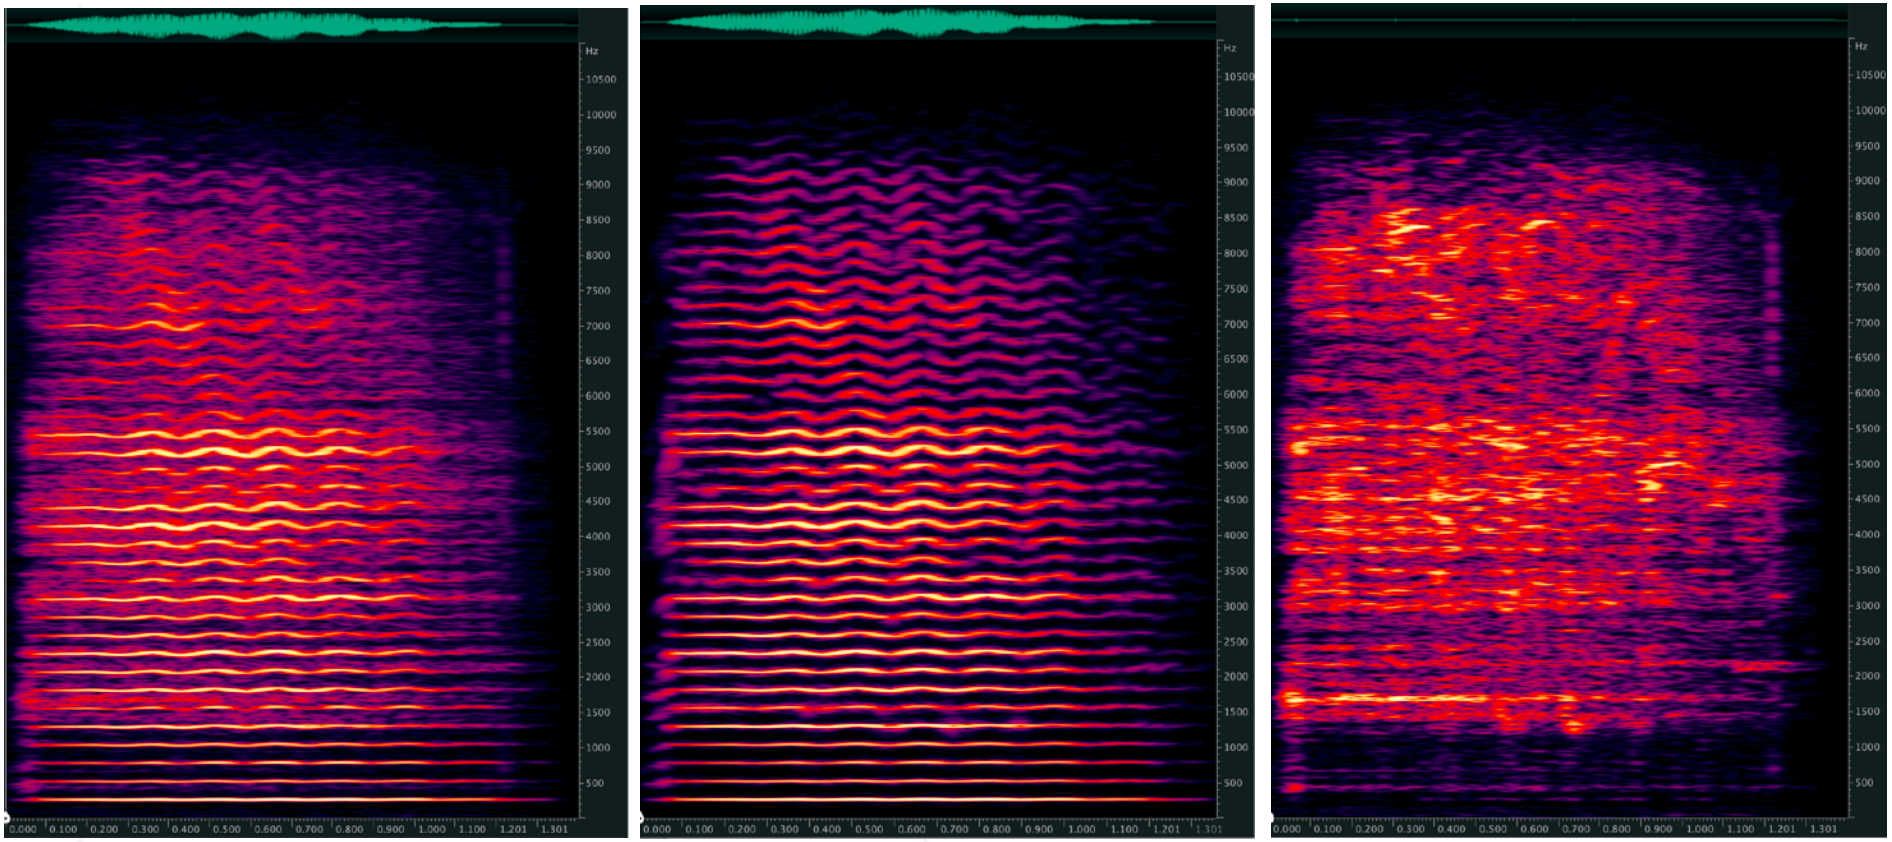
$x(t)$ $\hat{x}(t)$ $b(t) = x(t) - \hat{x}(t)$



Sinusoidal (harmonic) model

Examples: violin

$x(t)$ $\hat{x}(t)$ $b(t) = x(t) - \hat{x}(t)$



Sinusoidal (harmonic) model

Examples: sitar

$x(t)$ $\hat{x}(t)$ $b(t) = x(t) - \hat{x}(t)$

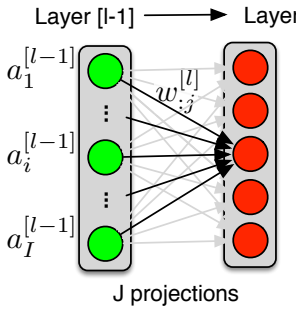
Multi-Layer-Perceptron (MLP)

- Extension of the Perception

- Neurons are organized into Layers which are Fully-Connected
  - $a_j^{[l]}$ is connected to all neurons $a_i^{[l-1]}$
  - connection done through
    - multiplications by weights $w_{ij}^{[l]}$,
    - addition of a bias $b_j^{[l]}$,
    - passing through non-linear activation $g(.)$
  - Each $\mathbf{w}_j^{[l]}$ defines a specific projection of the previous layer

Fully Connected Neural Network



$$a_j^{[l]} = g(\sum_i a_i^{[l-1]} w_{ij}^{[l]} + b_j^{[l]})$$

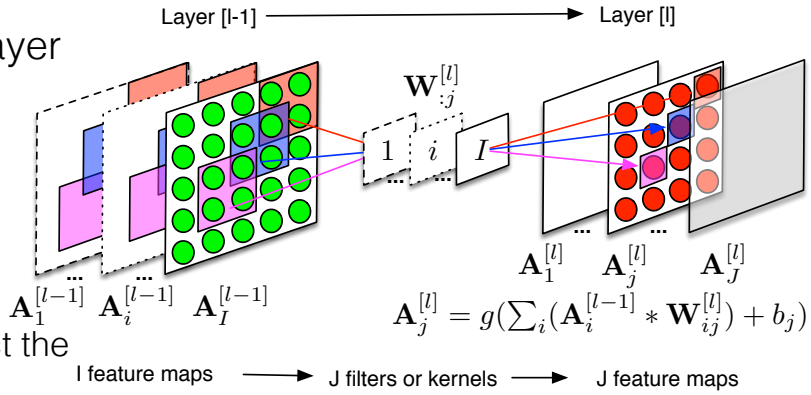
$$\mathbf{a}^{[l]} = g(\mathbf{a}^{[l-1]} \mathbf{W}^{[l]} + \mathbf{b}^{[l]})$$

[Frank Rosenblatt, "**The perceptron, a perceiving and recognizing automaton**" Project Para. Cornell Aeronautical Laboratory, 1957] LINK

Convolutional Neural Network (CNN)

- (1) Assume local connectivity of neurons of a given layer (vision: nearby pixels more correlated)
  - Each region (x, y) of $\mathbf{A}_i^{[l-1]}$ is projected individually
  - Results= feature map noted $\mathbf{A}_{i \to j}^{[l]}$ for the j^{th} projection
- (2) Add a **parameter sharing** property
  - for a given j, the same projection $\mathbf{W}_{ij}^{[l]}$ is used to project the different regions $(x, y) \rightarrow$ the weights are shared
  - apply the same projection to the various regions (x, y)
- (1)+(2) $\rightarrow$ convolution operator
- In practice
  - several input feature maps $\mathbf{A}_{1 \ldots i \ldots I}^{[l-1]}$, projection with a tensor $\mathbf{W}_{:j}^{[l]}$ (extends over I)
  - Results: feature map $\mathbf{A}_j^{[l]}$
  - Several projections: J different convolutions resulting in J output feature maps
- To reduce dimensionality, allows spatial invariance:
  - **max-pooling**

Convolutional Neural Network



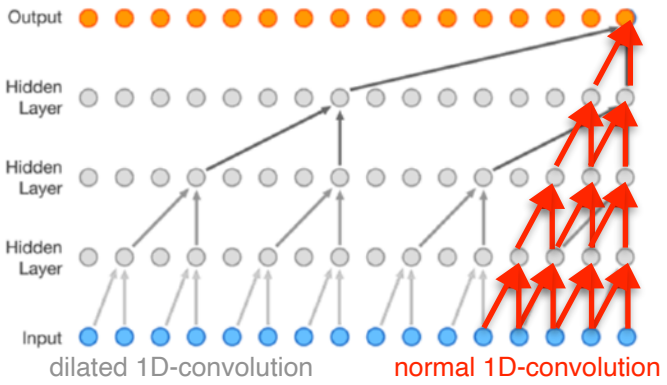
[K. Fukushima et al., "**Neocognitron: A self-organizing neural network model for a mechanism of visual pattern recognition**". In Competition and cooperation in neural nets, 1982]
[Y. LeCun, Léon Bottou, Yoshua Bengio, and Patrick Haner. "**Gradient- based learning applied to document recognition**". Proceedings of the IEEE, 86(11):2278–2324, 1998]

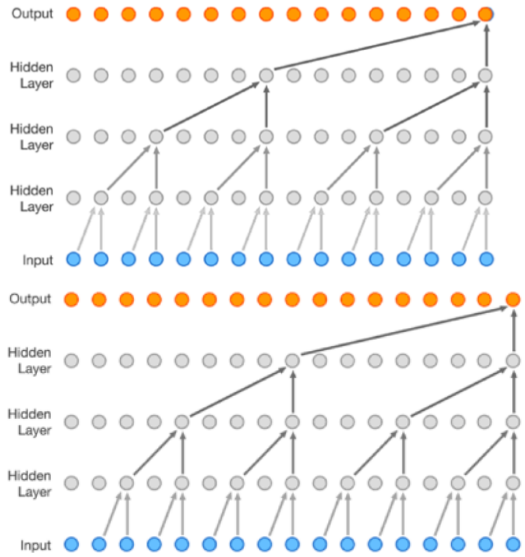
Temporal Convolutional Networks (TCN)

- Motivation: learn better projections than Fourier
- 1D-convolution applied on the raw audio waveform $x(n)$
  - filters $\mathbf{W}_j$ have only one dimension (time)
  - convolution is done over time

- Receptive field (RC)
  - portion of the input data to which a given neuron responds
  - images (256x256): only a few layers is necessary in CV to make the RC of a neuron cover the whole input image
  - audio (44100/sec): requires a huge number of layers

- 1D-Dilated- Convolutions
  - $(x \circledast_d w)(n) = \sum_{i=0}^{l-1} w(i)x(n-(d\,.\,i))$
  - the filters is convolved with the signal only considering one over d values





[A. van den Oord et al. "**Wavenet: A generative model for raw audio**", 2016] LINK

Temporal Convolutional Networks (TCN)

- 1D-Convolution
- + causality constraint
- + stacks two dilated-convolutions on top of each other (with weight-normalization, ReLu, DropOut)
- + with a parallel residual path

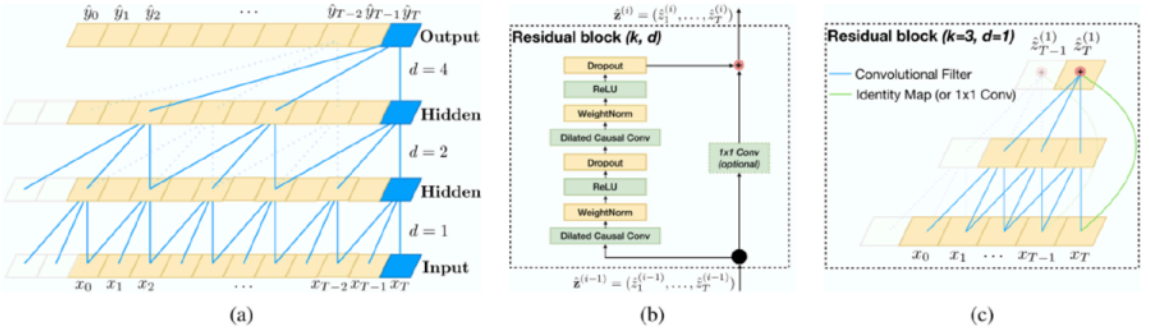


Figure 1. Architectural elements in a TCN. (a) A dilated causal convolution with dilation factors $d = 1, 2, 4$ and filter size $k = 3$. The receptive field is able to cover all values from the input sequence. (b) TCN residual block. An 1x1 convolution is added when residual input and output have different dimensions. (c) An example of residual connection in a TCN. The blue lines are filters in the residual function, and the green lines are identity mappings.

[Shaojie Bai et al. "**An empirical evaluation of generic convolutional and recurrent networks for sequence modeling**", 2018] LINK

Recurrent Neural Network (RNN)

- RNNs take into account the sequential aspect of the data
  - RNNs have a memory that keeps track of previously proposed events of the sequence
  - Internal/hidden representation of the data at time t, $\mathbf{a}^{<t>}$ does not only depend on the input data $\mathbf{x}^{<t>}$ but also on the internal/ hidden representation at the previous time $\mathbf{a}^{<t-1>}$

- More sophisticated RNN cells
  - Long Short Term Memory (LSTM)
  - Gated Recurrent Units (GRU)

Recurrent Neural Network

$$\mathbf{a}^{<t>} = g(\mathbf{x}^{<t>}\mathbf{W}_{xa} + \mathbf{a}^{<t-1>}\mathbf{W}_{aa} + \mathbf{b}_a)$$

ASR: Automatic Speech Recognition

History

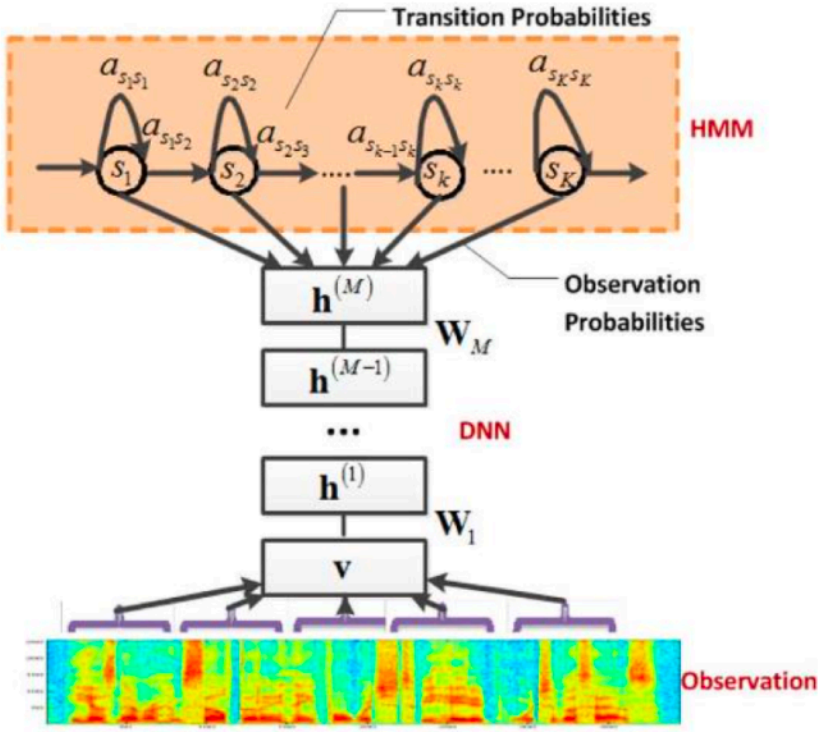
- **1990s**
  - Large vocabulary continuous dictation
- **2000s**
  - Discriminative training (minimize word/phone error r
- **2010s**
  - Deep learning significantly reduce error rate



source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Speech: Automatic Speech Recognition

Traditional approach: GMM-HMM

Traditional approach: GMM-HMM

- **Goal of Automatic Speech Recognition ?**
  - Find the most likely sentence (word sequence) W, which transcribes the speech audio A

$$\hat{W} = \arg\max_{W} P(W \mid A)$$
$$= \arg\max_{W} P(A \mid W) P(W)$$

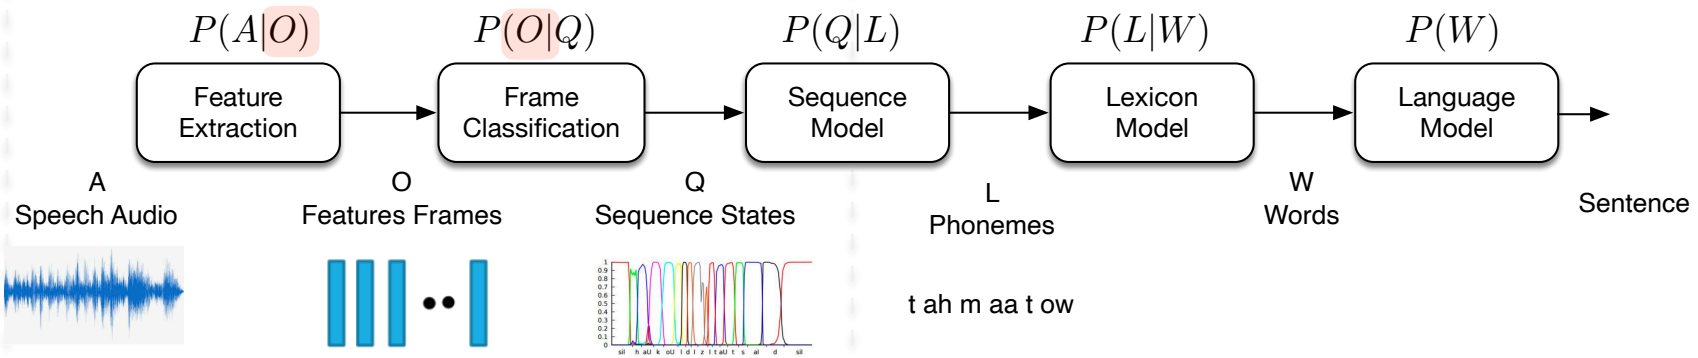
    - $P(A \mid W)$: the **acoustic** model
    - $P(W)$: the **language** model

- **Training ?**
  - Find the parameters of the acoustic and language models separately
    - Speech Corpus : speech waveform and human-annotated transcriptions
    - Language model : with extra data (prefer daily expressions corpus for spontaneous speech)

Traditional approach: GMM-HMM

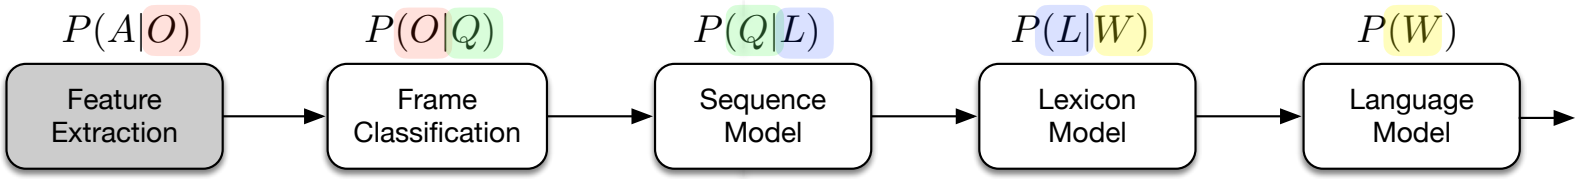
– **Architecture of Speech Recognition**

$$\hat{W} = \arg\max_W P(W|A)$$
$$= \arg\max_W P(A|W)P(W)$$
$$= \arg\max_W P(A|O)P(O|Q)P(Q|L)P(L|W)P(W)$$

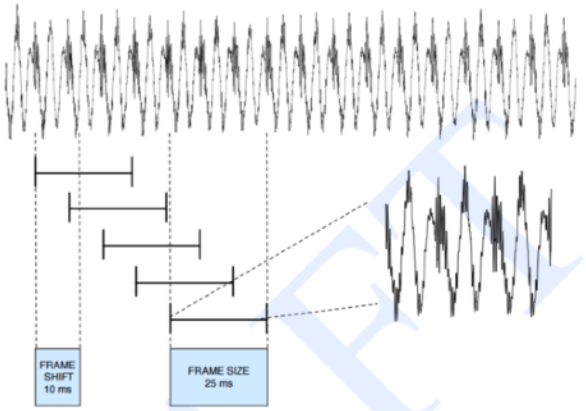


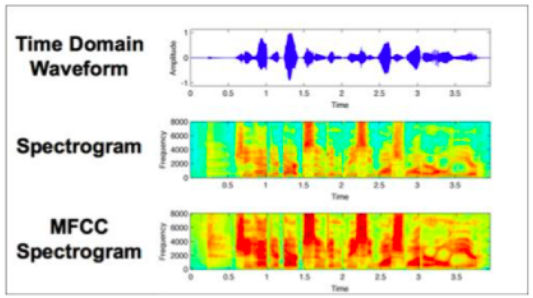
source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Traditional approach: GMM-HMM



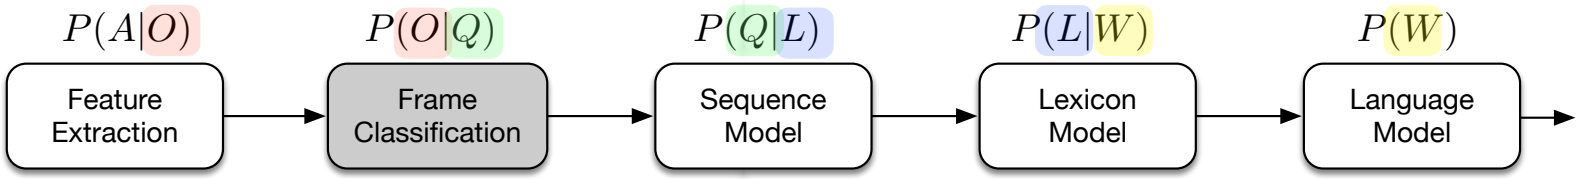
- $P(A \mid O) = P(Audio \mid Features)$
- **Feature extraction**
  - Raw waveforms are transformed into a sequence of featu approaches
  - Time domain to frequency domain





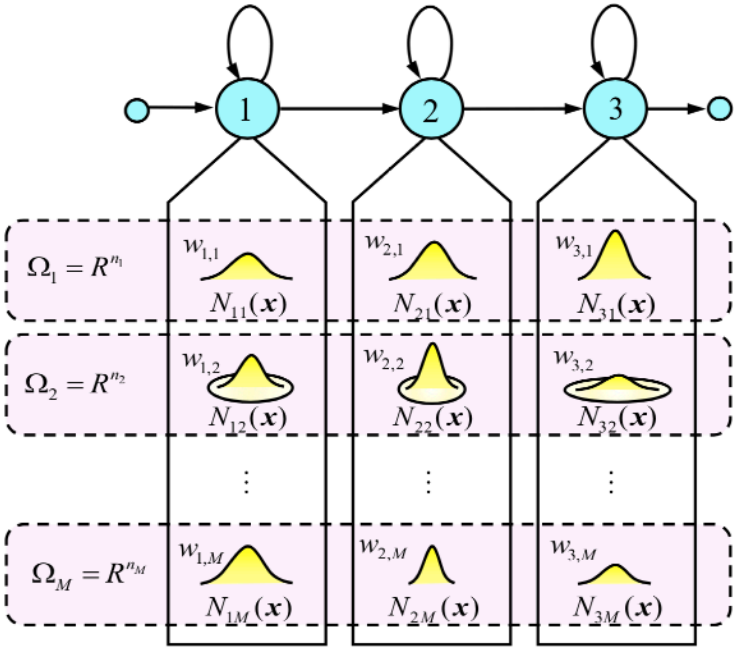
source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Traditional approach: GMM-HMM



- $P(O|Q) = P(Features|States)$
- **Frame Classification**
  - Gaussian Mixture Model (GMM)
    - Output probability is modeled by a mixture c

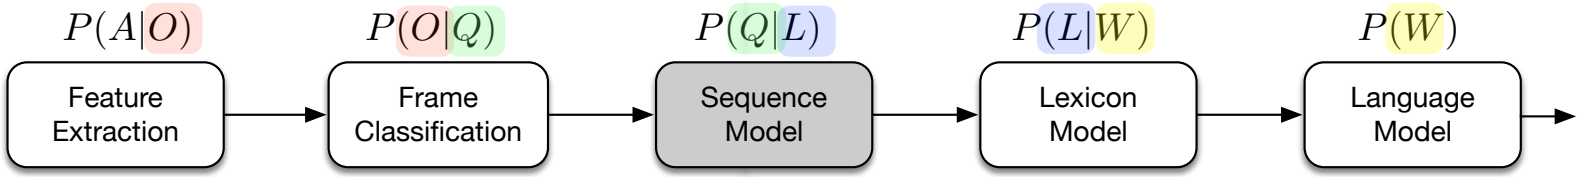
$$b_q(o_t) = b(o_t|q_t)$$
$$= \sum_{m=1}^{M} \mathcal{N}(o_t|\mu_m, \Sigma_m)$$



source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

ASR: Automatic Speech Recognition

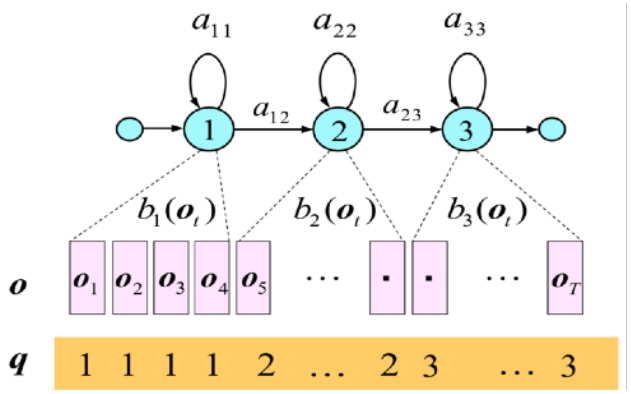
Traditional approach: GMM-HMM



- $P(Q|L) = P(States|Phonemes)$
- **Sequence model**
  - Hidden Markov Models (HMM)
    - The Markov chain whose state sequence is u

      a_{ij}: state transition probability

      $b_q(o_t)$: output probability

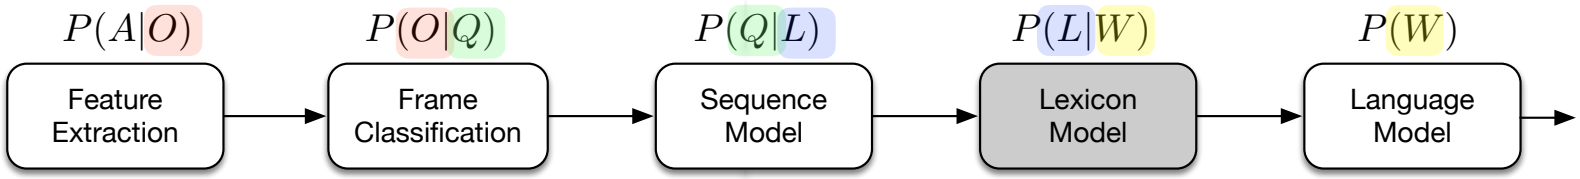


- Context Dependent Model
  - "We **w**ere away with William in Sea **W**orld"

  - Realization of **w** varies but similar patterns occur in the similar context

source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Traditional approach: GMM-HMM



- $P(L|W) = P(Phonemes|Words)$
- **Lexicon model**
  - Lexical modelling forms the bridge between the acoustic and language models
  - Prior knowledge of language
  - Mapping between words and the acoustic units (phoneme is most common)

Deterministic

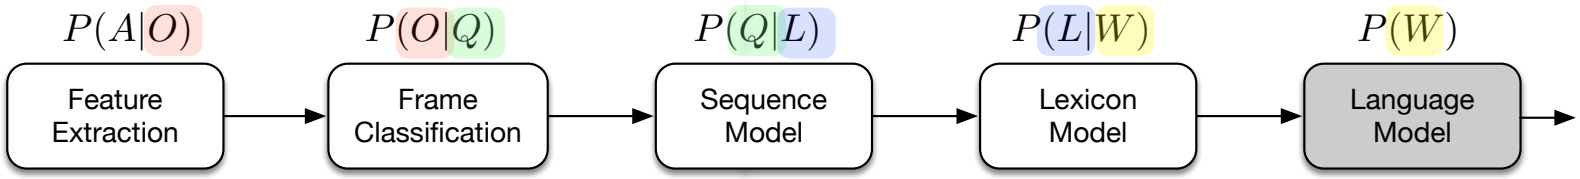
Word	Pronunciation
TOMATO	t ah m aa t ow
	t ah m ey t ow
COVERAGE	k ah v er ah jh
	k ah v r ah jh

Probabilistic

Word	Pronunciation	Probability
TOMATO	t ah m aa t ow	0.45
	t ah m ey t ow	0.55
COVERAGE	k ah v er ah jh	0.65
	k ah v r ah jh	0.35

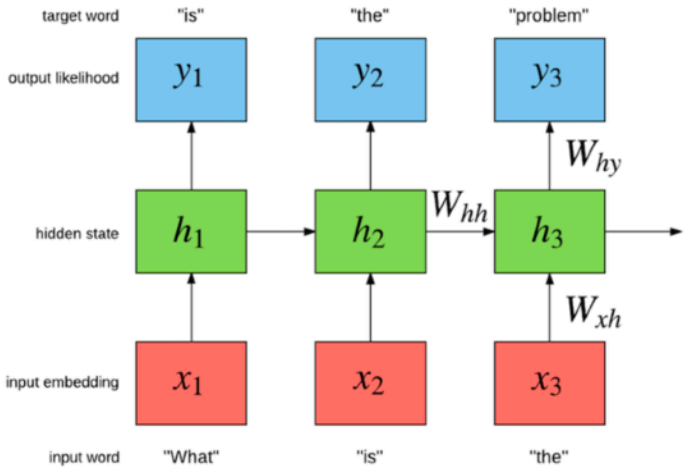
source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Traditional approach: GMM-HMM



- $P(W) = P(Words)$
- **Language model**
  - Language model is a probabilistic model used to
    - Guide the search algorithm (predict next word given history)
    - Disambiguate between phrases which are acoustically similar
      - "Great wine" vs "Grey twine"
  - It assigns probability to a sequence of tokens to be finally recognized
  - N-gram model $P(W_N | w_1, w_2, \ldots, w_{N-1})$

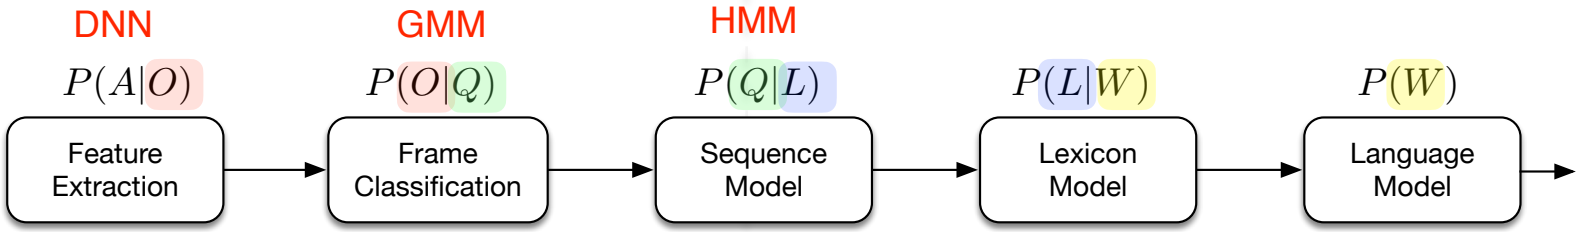
- using bi-grams, tri-grams
- using a Recurrent neural network



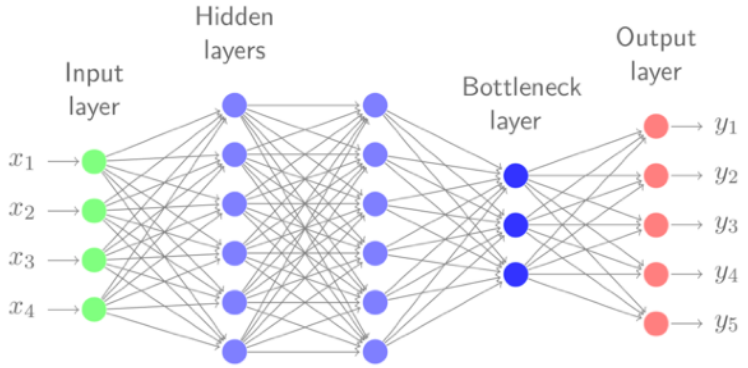
source : Yuchen Fan, Matt Potok, Christopher Shroba, "CS 598 LAZ : Cutting-Edge Trends in Deep Learning and Recognition"

Speech: Automatic Speech Recognition
Deep-learning approaches

Deep learning approaches: 1) DNN ⇒ GMM ⇒ HMM



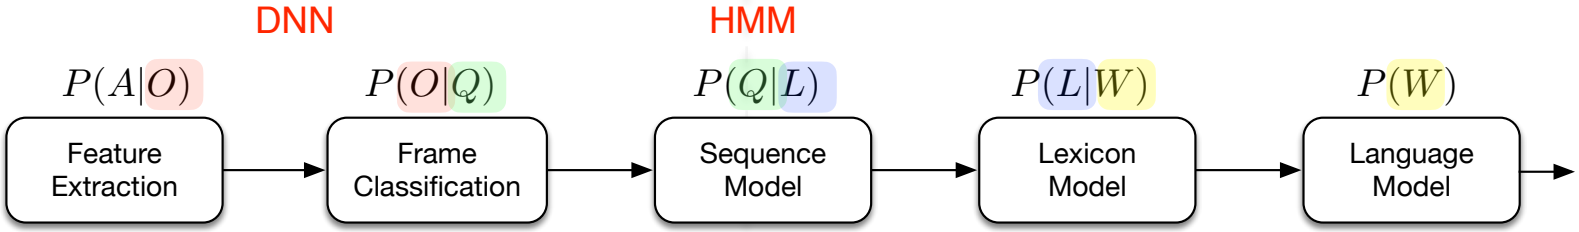
- **DNN / GMM / HMM**
  - Use neural networks to compute nonlinear feature rep
    - Trained audio features
    - Tandem, Bottleneck, DNN-derived features
    - Low-dimensional representation is modeled conventionally with GMMs
    - Allows all the GMM machinery and tricks to be exploited



- **How?**
  - Train a neural network to discriminate classes.
  - Use output or a low-dimensional bottleneck layer representation as features.
- **TRAP :**
  - Concatenate PLP-HLDA features and NN features.

H. Hermansky et al. "Tandem connectionist feature extraction for conventional HMM systems", 2000, IEEE ICASSP

Deep learning approaches: 1) DNN ⇒ HMM



– **DNN / HMM**

- Use neural networks (DNN) instead of GMM to estimate phonetic unit probabilities
  - Perform frame classification using a DNN
  - Classify acoustic features for state labels
  - Take softmax output as a posterior $P(state \mid o_t) = p(q_t \mid o_t)$
  - Work as output probability in HMM

$$p(o_t \mid q_t) = \frac{p(q_t \mid o_t) p(o_t)}{p(q_t)}$$

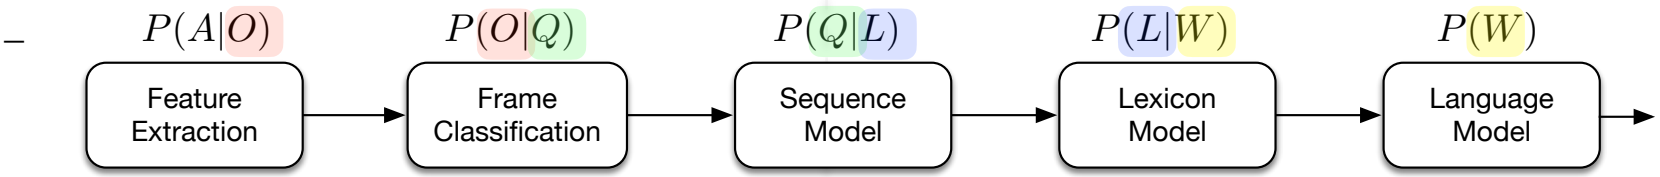
- where $p(q_t)$ is the prior probability for states

- Train the network as a classifier with a softmax across the phonetic units.
  - Train with cross-entropy.
  - Softmax $y(i) = \frac{\exp(a_\theta(i))}{\sum_{j=1}^{N} \exp(a_\theta(j))}$
  - will converge to posterior across phonetic states $p(q_i \mid o_t)$

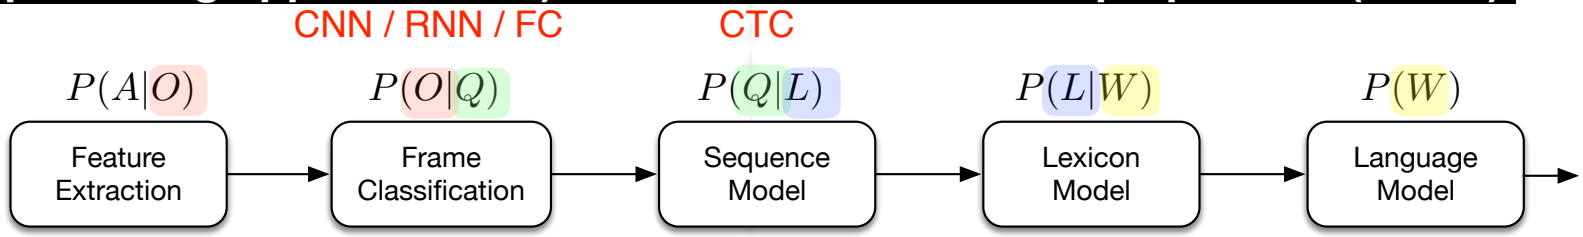
G. Hinton, et al. "Deep Neural Networks for Acoustic Modeling in Speech Recognition". 2012, Signal Processing Magazine

Deep learning approaches: 3) End-to-End models: LSTM CTC

CNN / RNN / FC CTC



Deep learning approaches: 3) End-to-End models: Deep Speech 2 (Baidu)



- 3 layers of 2D-invariant convolution
- 7 layers of bidirectional simple recurrence 100M para
- Word error rates

Test set	Deep speech 2	Human

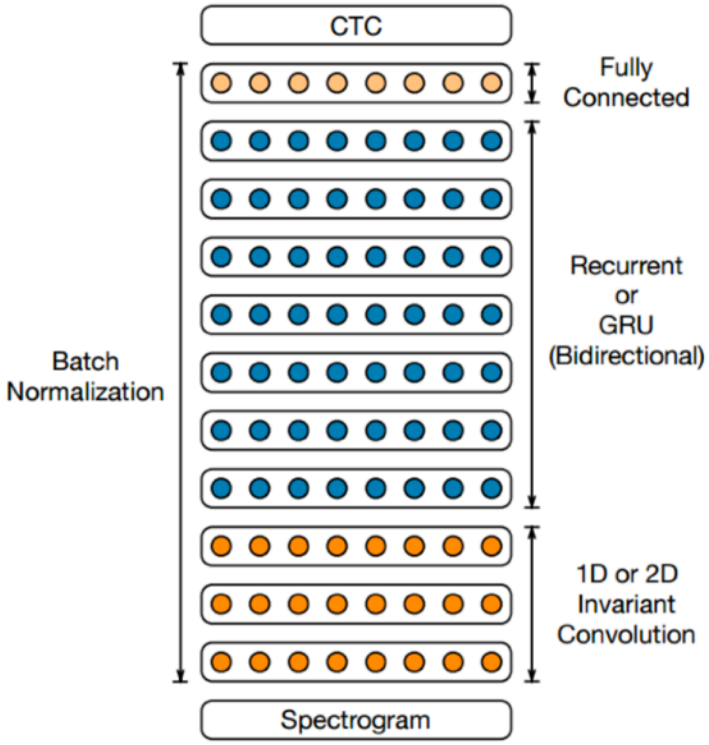
LibriSpeech test-clean	5.33	5.83
LibriSpeech test-other	13.25	12.69

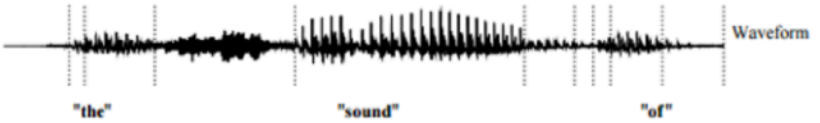


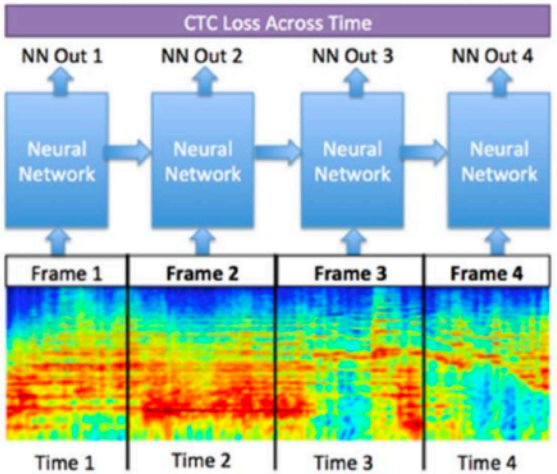
Connectionist Temporal Classification

Connectionist Temporal Classification

Goal

- end-to-end training
  - from audio/spectrogram to characters
- can be combined with a language model
- neural network is usually a stack of bi-LSTM





Problem

- for training and decoding :
  - output Y (the characters) need to be aligned with input X(the audio/spectrogram)
- in practice input and output have different length ($T_y \neq T_x$)
- manual alignment very costly (cannot at scale)

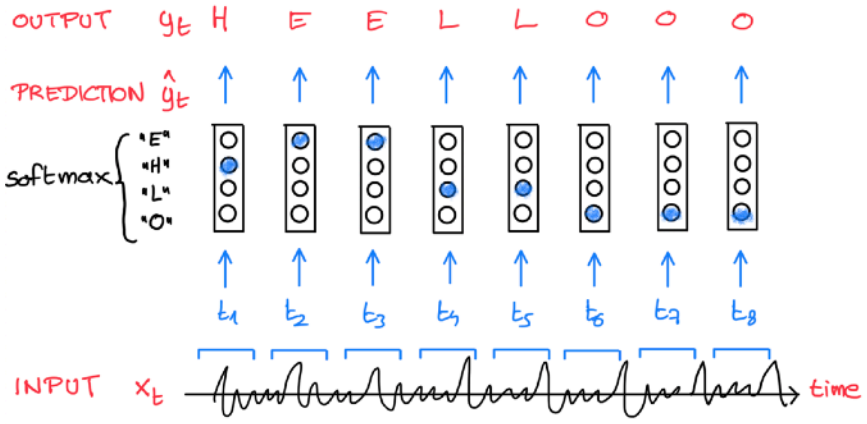
Solution

- Connectionist temporal classification
- Transform the output such that $T_y = T_x$

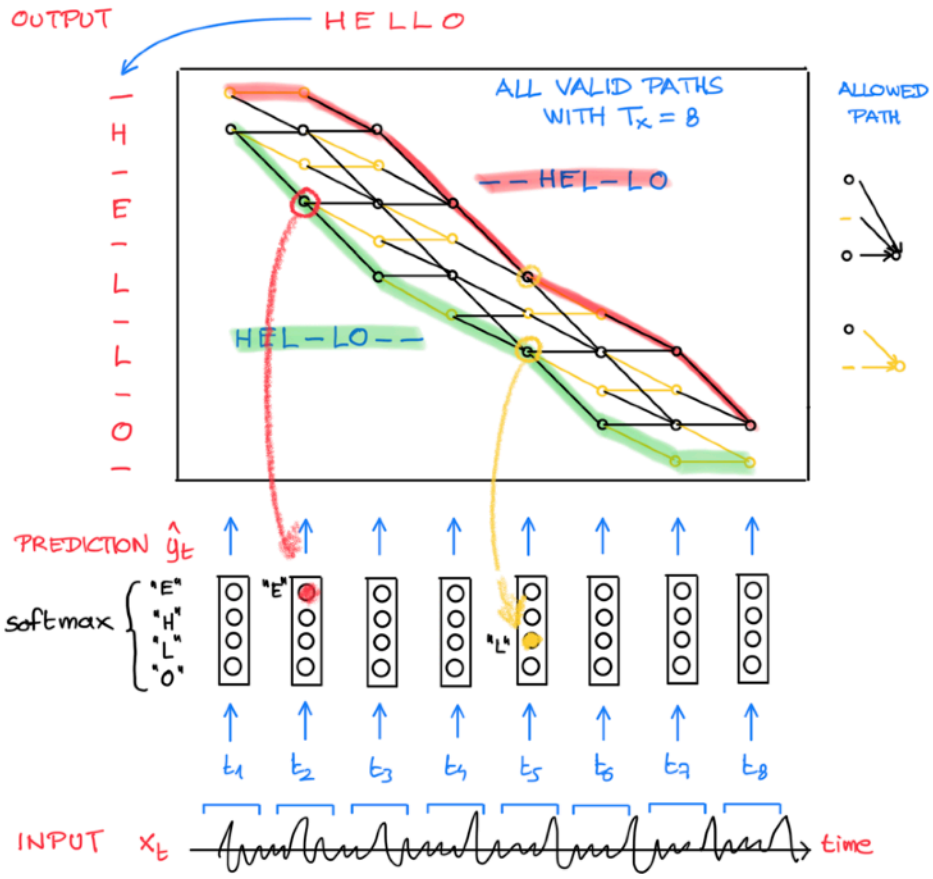
[A. Graves et al."Connectionist temporal classification: labelling unsegmented sequence data with recurrent neural networks", ICML, 2006] Link
[W. Gharbieh, "Connectionist Temporal Classification, Labelling Unsegmented Sequence Data with RNN"] Link
[A. Hannun "Sequence Modeling With CTC"] https://distill.pub/2017/ctc/

Connectionist Temporal Classification

Strongly aligned



Weakly aligned data

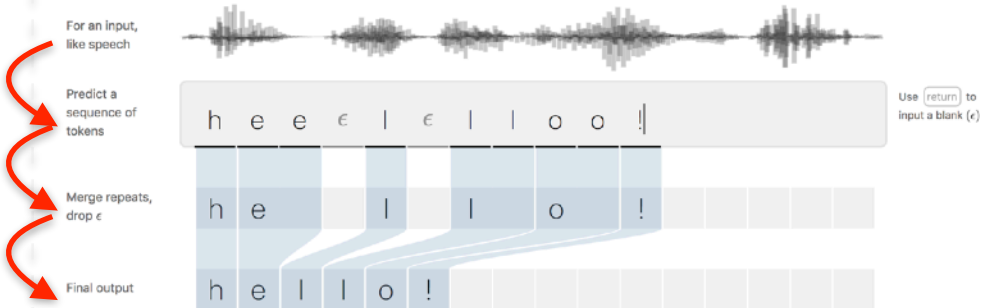


[A. Graves et al."Connectionist temporal classification: labelling unsegmented sequence data with recurrent neural networks", ICML, 2006] Link

Decoding

- **Network**:
  - $\mathbf{y} = f_\theta(\mathbf{x}) \quad (\mathbb{R}^m)^T \mapsto (\mathbb{R}^n)^T$
  - y_t^k probability of observing output unit k at time t
- y_t^k over the alphabet $L' = L \cup \{blank\}$
  - L={a, b, ..., z}: the possible characters
  - + a blank symbol ("ϵ" or "-")
- To get the final text
  - define a many-to-one **mapping function** $\mathcal{B}$: transforms the sequence by merging identical characters if not separated by "ϵ" or "-"

- **Examples** :
  - $\mathcal{B}$("hell-loo") = $\mathcal{B}$("hel-lo") = "hello"
  - $\mathcal{B}$("hellllloo") = "helo"
  - $\mathcal{B}$("cc-a-tt") = $\mathcal{B}$("c-a-t") = "cat"
  - $\mathcal{B}$("-c-a-t–") = $\mathcal{B}$("-c-a-t-") = "cat"
  - $\mathcal{B}$("c-aaa-at") = $\mathcal{B}$("c-a-at") = "caat"

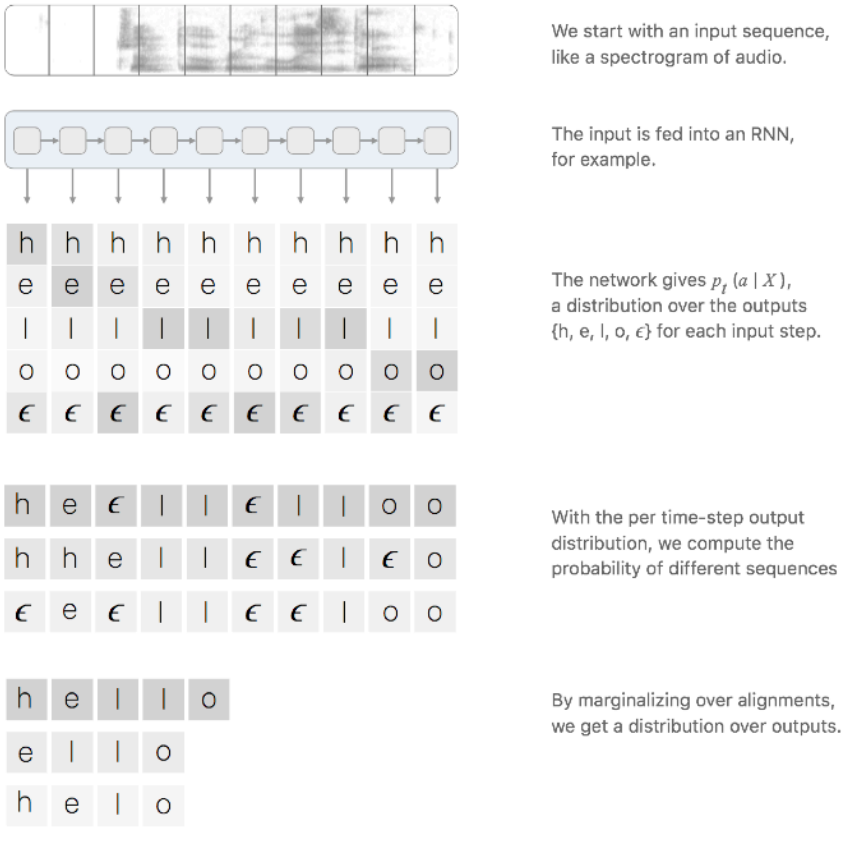


Training: maximise the probability $p(\mathbf{l}\,|\,\mathbf{x}) \Rightarrow$ minimise the CTC loss

- $p(\mathbf{l}\,|\,\mathbf{x})$?
  - we want to know how likely a given sentence $\mathbf{l}$ ="hello" is, given the input $\mathbf{x}$=spectrogram
  - T_x and T_y have different length
- **Alignements paths π**
  - we need to define the different possible "pronunciations" of $\mathbf{l}$="hello" such that it matches T_x
  - $\mathcal{B}^{-1}$("hello") for $T_x = T_y = 8$
    - "hel-looo", "hel-lloo", "hhhel-lo", "hheel-lo", . . .
- $p(\mathbf{l}\,|\,\mathbf{x})$
  - We sum up over all possible paths $\pi \in \mathcal{B}^{-1}(\mathbf{l})$

$$p(\mathbf{l}\,|\,\mathbf{x}) = \sum_{\pi \in \mathcal{B}^{-1}(\mathbf{l})} p(\pi\,|\,\mathbf{x})$$

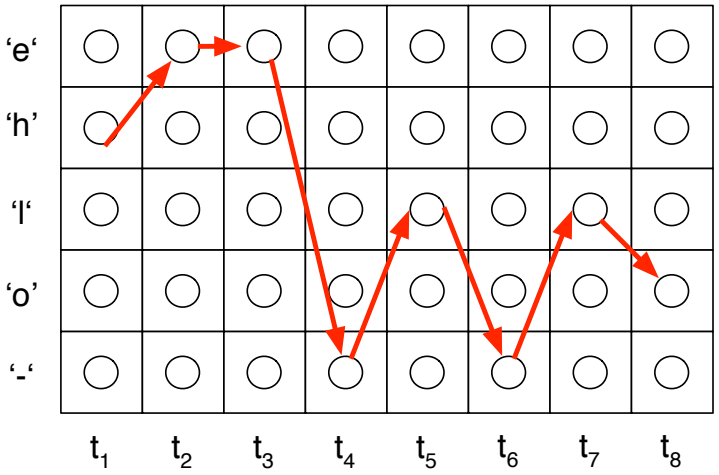
$$p(\pi\,|\,\mathbf{x}) = \Pi_{t=1}^{T} y_t^{\pi_t}$$



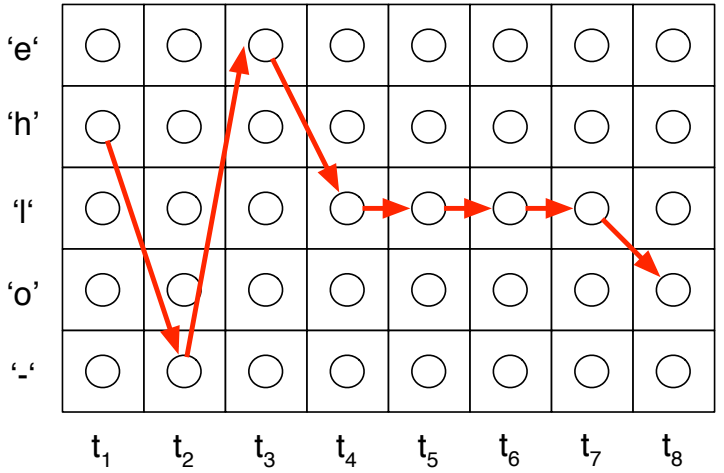
Training : minimise the CTC Loss

- CTCLoss = $-\log p(\mathbf{l})$
- **Example:**
  - for the world "hello", we wand to minimise $-\log p(''hello'')$
- **Problem:**
  - the number of alignement paths $\pi \in \mathcal{B}^{-1}(\mathbf{l})$ can quickly explode !
  - there are $5^8 = 390.625$ ways (possible paths) to go from t_1 to t_8
  - cannot be solved trivially

f('hee-l-lo')='hello'

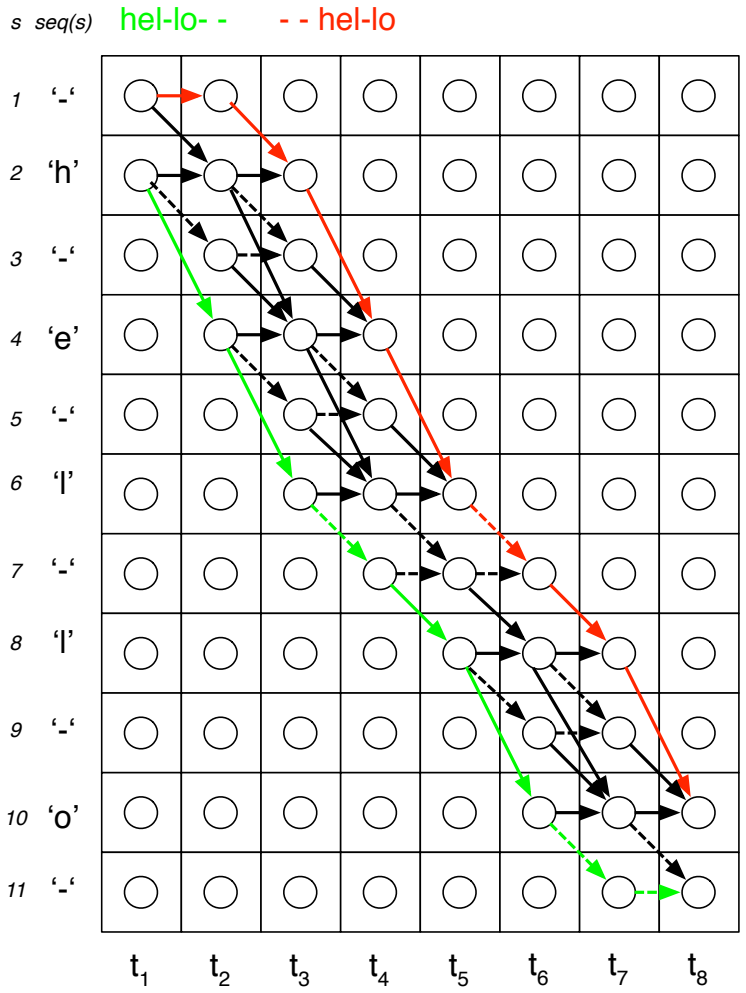


f('h-elllllo')='helo'

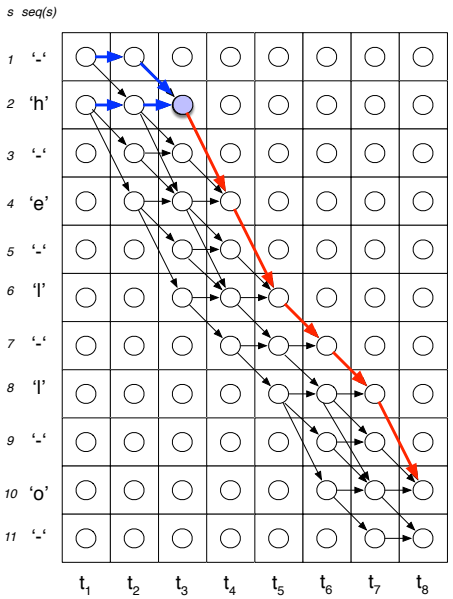


Training : the CTC Loss

- All possible paths $\pi \in \mathcal{B}^{-1}(\mathbf{l})$
  - Capture variations in pronunciation from $\mathcal{B}$("hel-lo--") to f("--hel-lo")



Training : the CTC Loss



– Complete path calculation example

– The **forward pass** gives

$$\alpha_{t_3}(2) = p(''--h'') + p(''-hh'') + p(''hhh'')$$

- $$= y_{t_1}^{''-''} y_{t_2}^{''-''} y_{t_3}^{''h''} + y_{t_1}^{''-''} y_{t_2}^{''h''} y_{t_3}^{''h''} + y_{t_1}^{''h''} y_{t_2}^{''h''} y_{t_3}^{''h''}$$

– The **backward pass** results in

$$\beta_{t_3}(2) = p(''hel-lo'')$$

- $$= y_{t_3}^{''h''} y_{t_4}^{''e''} y_{t_5}^{''l''} y_{t_6}^{''-''} y_{t_7}^{''l''} y_{t_8}^{''o''}$$

– The **final results**

$$\alpha_{t_3}(2)\beta_{t_3}(2) = y_{t_1}^{''-''} y_{t_2}^{''-''} y_{t_3}^{''h''} \cdot y_{t_3}^{''h''} y_{t_4}^{''e''} y_{t_5}^{''l''} y_{t_6}^{''-''} y_{t_7}^{''l''} y_{t_8}^{''o''}$$
$$+ y_{t_1}^{''-''} y_{t_2}^{''h''} y_{t_3}^{''h''} \cdot y_{t_3}^{''h''} y_{t_4}^{''e''} y_{t_5}^{''l''} y_{t_6}^{''-''} y_{t_7}^{''l''} y_{t_8}^{''o''}$$
$$+ y_{t_1}^{''h''} y_{t_2}^{''h''} y_{t_3}^{''h''} \cdot y_{t_3}^{''h''} y_{t_4}^{''e''} y_{t_5}^{''l''} y_{t_6}^{''-''} y_{t_7}^{''l''} y_{t_8}^{''o''}$$

- $$= \left[p(''--hel-lo'') + p(''-hhel-lo'') + p(''hhhel-lo'')\right] \cdot y_{t_3}^{''h''}$$

– Total probability of all paths going through $''h''$ at t_3

- $$\frac{\alpha_{t_3}(2)\beta_{t_3}(2)}{y_{t_3}^{''h''}}$$

Training : the CTC Loss

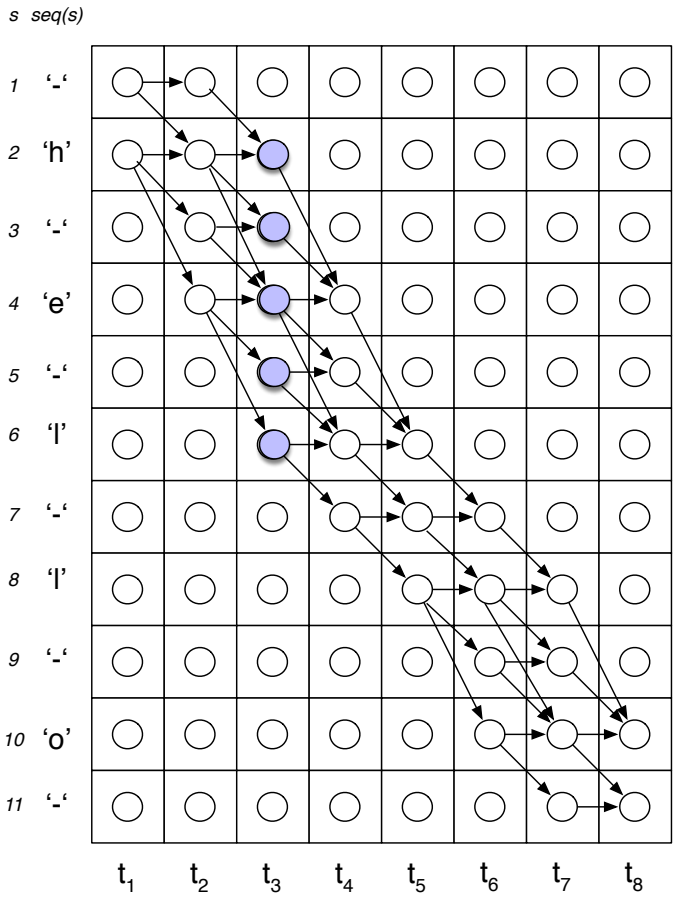
– **Calculating the Loss at a particular time-step example**

– $p(''hello'')$ at $t = 3$ is the sum of the probabilities of all paths through all the symbols

- $$p(''hello'') = \sum_{s=2}^{6} \frac{\alpha_{t_3}(s)\beta_{t_3}(s)}{y_{t_3}^{seq(s)}}$$

– In general, the probability of the ground label is

- $$p(''hello'') = \sum_{s=1}^{|seq|} \frac{\alpha_t(s)\beta_t(s)}{y_t^{seq(s)}}$$



Training : the CTC Loss

– **How to do back-propagation ?**

- $$\frac{\delta - \log p(''hello'')}{\delta y_t^k} = \frac{-1}{p(''hello'')} \frac{\partial p(''hello'')}{\partial y_t^k}$$

– since

- $$p(''hello'') = \sum_{s=1}^{|seq]} \frac{\alpha_t(s)\beta_t(s)}{y_t^{seq(s))}}$$

– we have

- $$\frac{\partial p(''hello'')}{\partial y_t^k} = \frac{1}{(y_t^k)^2} \sum_{s:seq(s)=k} \alpha_t(s)\beta_t(s)$$

Training : the CTC Loss

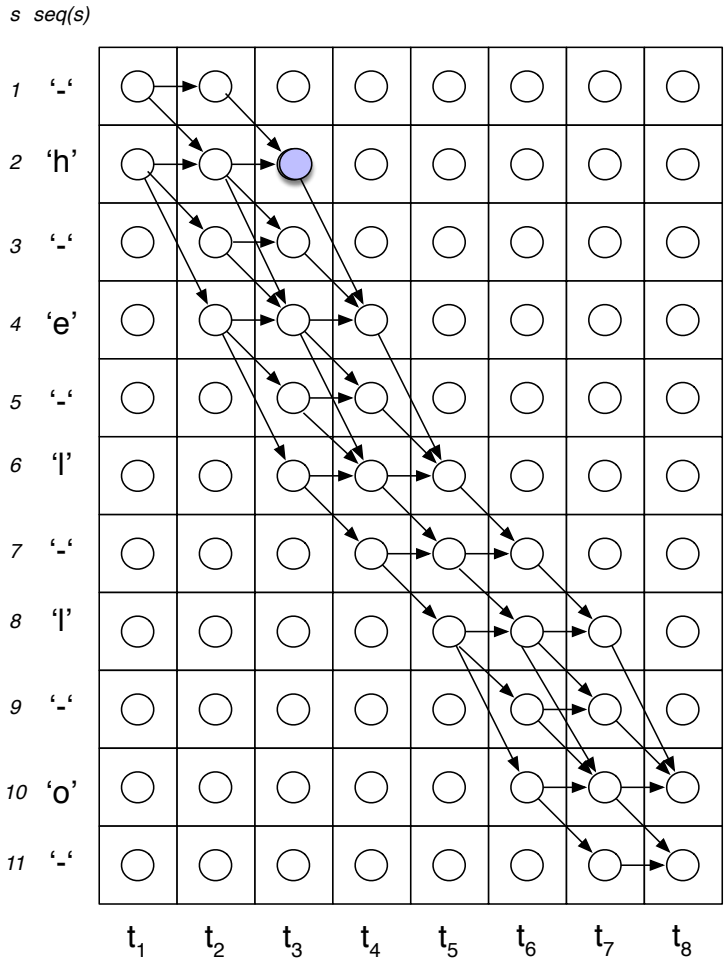
– **Back-propagation example 1**

– Given

- $$\frac{\partial p(''hello'')}{\partial y_t^k} = \frac{-1}{(y_t^k)^2} \sum_{s:seq(s)=k} \alpha_t(s)\beta_t(s)$$

– For $t = 3$ and $k = '' h''$

- h occurs at $s = 2$
- $$\frac{\partial p(''hello'')}{\partial y_{t_3}^{''h''}} = \frac{-1}{(y_{t_3}^{''h''})^2} \alpha_{t_3}(2)\beta_{t_3}(2)$$



Training : the CTC Loss

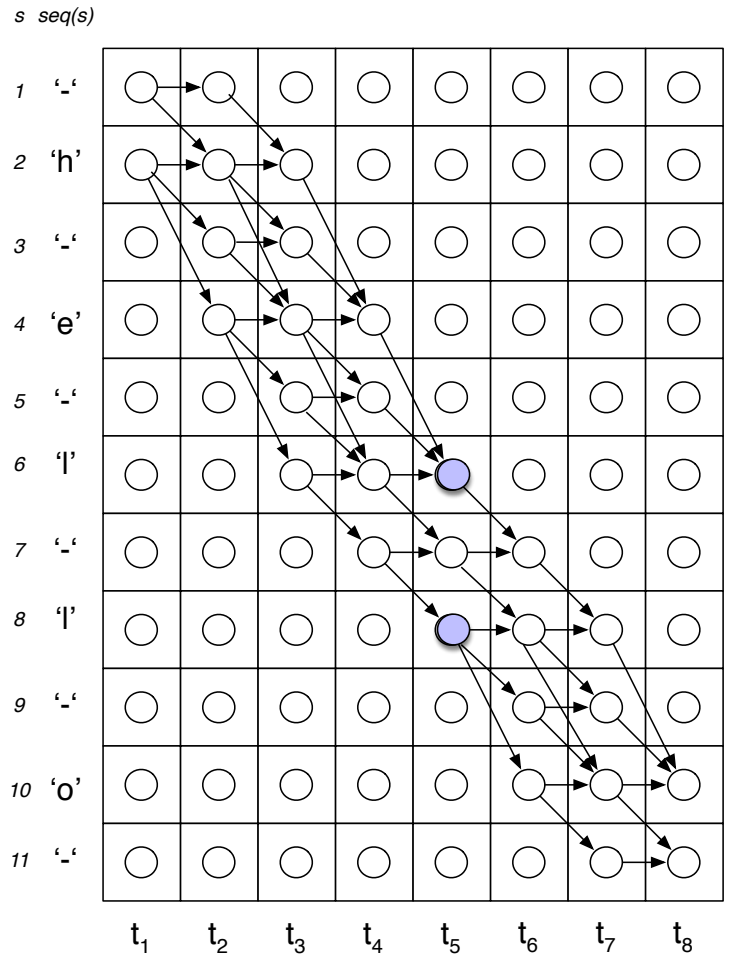
– **Back-propagation example 2**

– Given

- $$\frac{\partial p(''hello'')}{\partial y_t^k} = \frac{-1}{(y_t^k)^2} \sum_{s:seq(s)=k} \alpha_t(s)\beta_t(s)$$

– For $t = 5$ and $k = '' \, l''$

- l occurs at $s = 6$ and $s = 8$
- $$\frac{\partial p(''hello'')}{\partial y_{t_5}^{''l''}} = \frac{-1}{(y_{t_5}^{''h''})^2}[\alpha_{t_5}(6)\beta_{t_5}(6) + \alpha_{t_5}(8)\beta_{t_5}(8)]$$



CTC vs Framewise

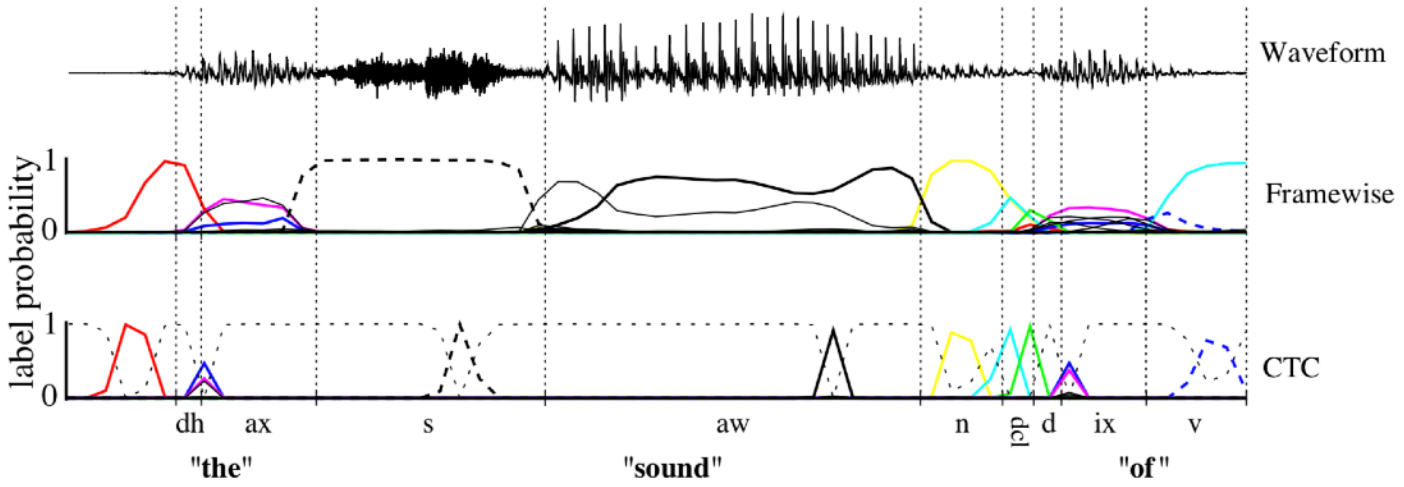


Figure 1. **Framewise and CTC networks classifying a speech signal**. The shaded lines are the output activations, corresponding to the probabilities of observing phonemes at particular times. The CTC network predicts only the sequence of phonemes (typically as a series of spikes, separated by 'blanks', or null predictions), while the framewise network attempts to align them with the manual segmentation (vertical lines). The framewise network receives an error for misaligning the segment boundaries, even if it predicts the correct phoneme (e.g. 'dh'). When one phoneme always occurs beside another (e.g. the closure 'dcl' with the stop 'd'), CTC tends to predict them together in a double spike. The choice of labelling can be read directly from the CTC outputs (follow the spikes), whereas the predictions of the framewise network must be post-processed before use.

Connectionist Temporal Classification

Example of results with CTC

AS OF APRIL FIRST ALL INTEREST INCOME WILL BE TAXED AT TWENTY PERCENT.

BLSTM-CTC transcribed grapheme string:

a s SP o f SP a i p r o l f i r s t SP a l SP i n t e r e s t SP i n c o m e SP w i l l SP b e SP t a x t SP i t SP t w e n t i n SP p e r c e n t SP

Final output after decoding:

AS OF APRIL FIRST AL **INTEREST INCOME WILL BE** TAX T. IT **TWENTY PERCENT.**

W SJ1 example sentence 1. Average recognition case. Manual annotation (top), BLSTM-CTC grapheme output-SP denotes short-pause, i.e. a word boundary (middle), BLSTM-CTC grapheme output after dictionary based (unweighted, no language model) decoding (bottom), see section III. Correctly recognised words are printed in bold-face.

Model	Prediction
Ground Truth	SILENCE
CTC	SILENCE
RNN-Transducer	SILENCE
Attention	i want to get to get to get to get to get to get to get to do that
Ground Truth	play the black eyed peas songs
CTC

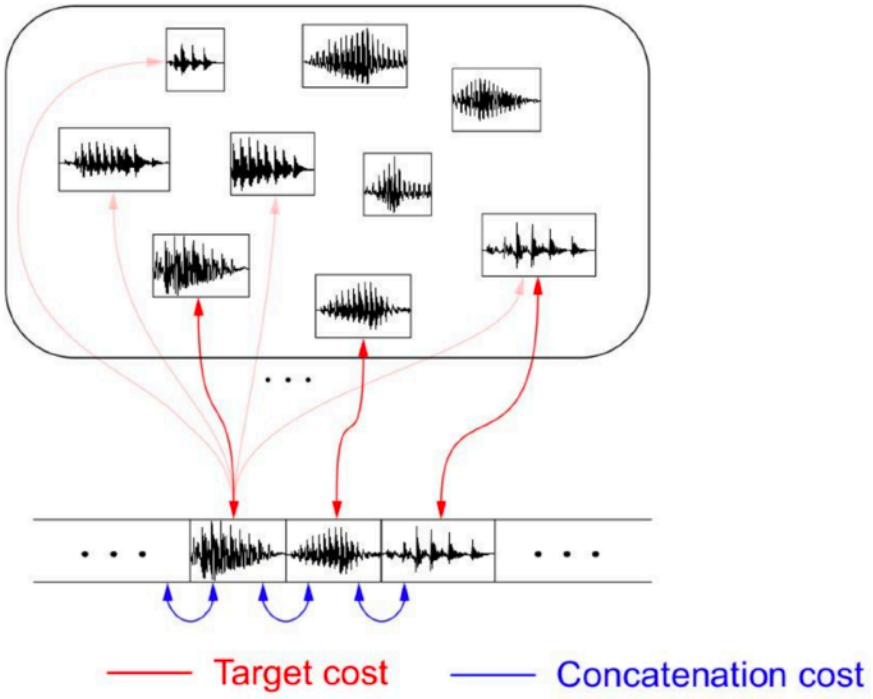
Application: multi-f0 estimation, DDSP

TTS : Text To Speech
Traditional approach : 1) Concatenative synthesis

Concatenative speech synthesis

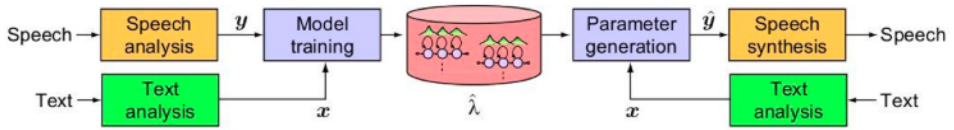
- Unit selection and concatenation
  - Concatenate best pre-recorded speech units
  - Target cost + Concatenation cost
- Criteria :
  - Intelligibility
  - Naturalness

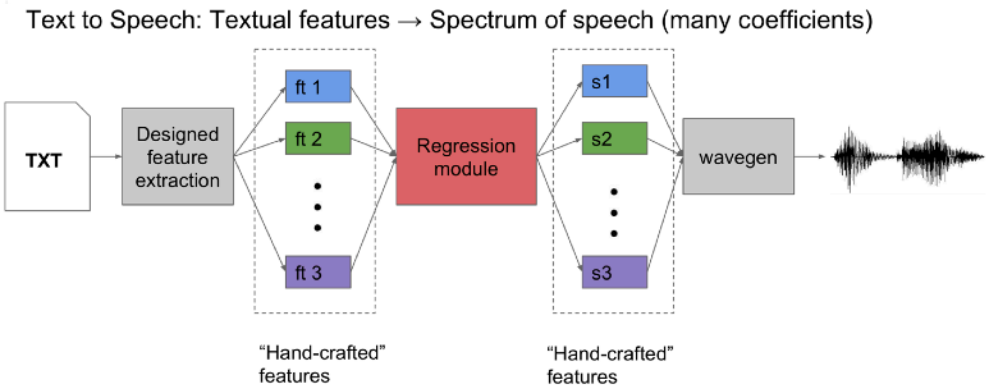


TTS : Text To Speech
Traditional approach : 2) Statistical Speech Synthesis

Statistical Speech Synthesis

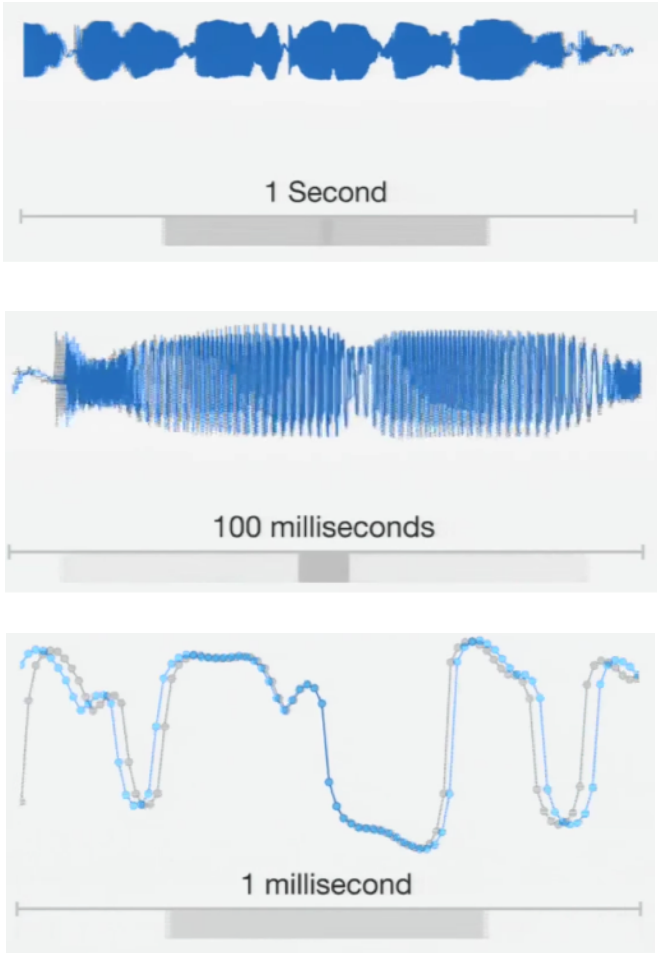
- 1) Represent speech waveform using parameters
  - from text to phoneme (pronunciation)
  - from phoneme to phoneme (with linguistic features)
  - speech features : phoneme duration, fundamental frequency, cepstra
- 2) Use statistic generative model
  - Regression of the parameters using HMM
- 3) Reconstruct waveform from generated parameters
  - vocoder (phase reconstruction)





2016 → WaveNet

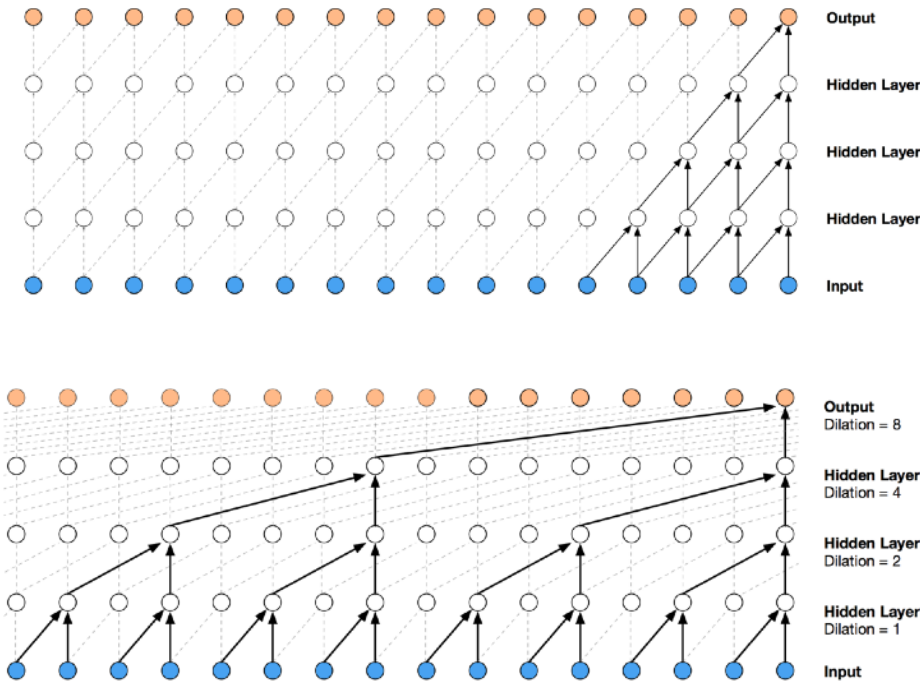
- **Generative model operating directly on audio samples**
  - raw audio = challenging to model because structure at very different scales
  - Based on PixelCNN
  - High resolution signal and long-term dependencies
    - dependencies at **different level**
- **Auto-regressive model**
  - next sample is (almost) reconstructed from **linear** causal combination of past samples
  - $p(x_1, x_2, \ldots, x_T) = \prod_{t=1}^{T} p(x_t \mid x_1, \ldots, x_{t-1})$
  - $x_t = \sum_{p=1}^{P} \alpha_t x_{t-p} + \epsilon_t$
- **Neural Auto-regressive model:**
  - $x_t = f_\theta(x_1, \ldots, x_{t-1})$



[A. Van Den Oord et al., "**WaveNet : A generative model for raw audio**", 2016] LINK
[S. Mehri et al. "**Sample-RNN: An unconditional end-to-end neural audio generation model**", In ICLR, 2017] LINK

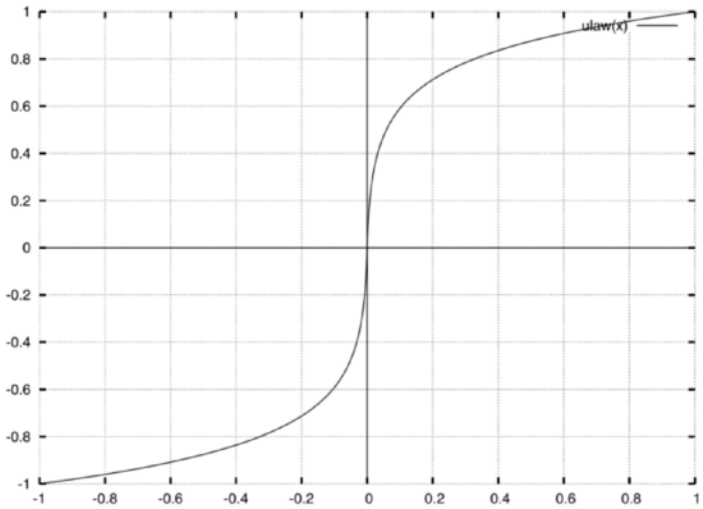
2016 → WaveNet

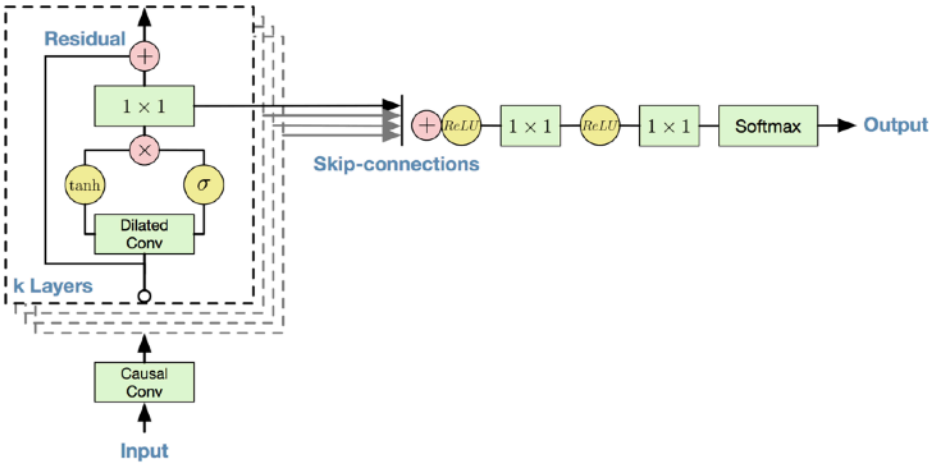
- **Neural Auto-regressive model:**
  - $x_t = f_\theta(x_1, \ldots, x_{t-1})$
  - using RNN ⇒ costly
  - using CNN ⇒ cheap (all convolution can be done in parallel)
- **Causal Convolution**
  - problem : require many layers, or large filters to increase the receptive field.
- **Dilated Convolution** (convolution à trou) :
  - skipping input values with a certain step
  - increase the receptive field by orders of magnitude
- **Stacked dilated convolutions**
  - dilation is doubled for every layer up to a limit and then repeated
    - 1,2,4,...,512,1,2,4,...,512,1,2,4,..., 512.
- Generation is slow :
  - predictions sequential (2 m to generate 1 s)



2016 → WaveNet

- **Input/output signal representation**
  - using μ-law ⇒ 8 bits ⇒ 256 categories
  - $f(x_t) = \text{sign}(x_t)\frac{\log(1+\mu|x_t|)}{\log(1+\mu)}$
    - with $-1 < x_t < 1$ and $\mu = 256$
- **Softmax layer**
  - trained to maximize log-likelihood of the data w.r.t. parameters
- **Gated Activation Units**
  - $\mathbf{z} = \tanh(W_{f,k} * \mathbf{x}) \odot \sigma(W_{g,k} * \mathbf{x})$
  - with
    - $*$ the convolution
    - $\odot$ the element-wise multiplication
- **Residual and Skip connections**
  - to speed up convergence and enable training of much deeper models





- **Conditional Wavenet :** $p(\mathbf{x}\,|\,\mathbf{h}) = \prod_{t=1}^{T} p(x_t\,|\,x_1, \ldots, x_{t-1}, \mathbf{h})$
  - conditioning the model on other input variables $\mathbf{h}$

- **Global conditioning** (speaker ID, music genre, instruments)
  - $\mathbf{h}$: single latent representation
  - influences the output distribution across all time steps,
    - e.g. a speaker embedding in a TTS model
  - $\mathbf{z} = \tanh(W_{f,k} * \mathbf{x} + V_{f,k}^T \mathbf{h}) \odot \sigma(W_{g,k} * \mathbf{x} + V_{g,k}^T \mathbf{h})$
    - $V_{*,k}$ is a learnable linear projection
    - $V_{*,k}^T \mathbf{h}$ is broadcasted over the time dimension

- **Local conditioning** (text, linguistic features + f0 + duration model)
  - h_t: time series, possibly with a lower sampling frequency than the audio signal,
    - e.g. linguistic features in a TTS model
  - First transform this time series using a transposed convolutional network (learned upsampling)
    - (maps it to a new time series $\mathbf{y} = f(\mathbf{h})$with the same resolution as the audio signal
  - $\mathbf{z} = \tanh(W_{f,k} * \mathbf{x} + V_{f,k}^T * \mathbf{y}) \odot \sigma(W_{g,k} * \mathbf{x} + V_{g,k}^T * \mathbf{y})$

2016 → WaveNet

– **Perceptual MOS tests**

Speech samples	Subjective 5-scale MOS in naturalness	
	North American English	Mandarin Chinese
LSTM-RNN parametric	3.67 ± 0.098	3.79 ± 0.084
HMM-driven concatenative	3.86 ± 0.137	3.47 ± 0.108
WaveNet (L+F)	$\mathbf{4.21} \pm 0.081$	$\mathbf{4.08} \pm 0.085$
Natural (8-bit μ-law)	4.46 ± 0.067	4.25 ± 0.082
Natural (16-bit linear PCM)	4.55 ± 0.075	4.21 ± 0.071

Table 1: Subjective 5-scale mean opinion scores of speech samples from LSTM-RNN-based statistical parametric, HMM-driven unit selection concatenative, and proposed WaveNet-based speech synthesizers, 8-bit μ-law encoded natural speech, and 16-bit linear pulse-code modulation (PCM) natural speech. WaveNet improved the previous state of the art significantly, reducing the gap between natural speech and best previous model by more than 50%.

Making Music

Since WaveNets can be used to model any audio signal, we thought it would also be fun to try to generate music. Unlike the TTS experiments, we didn't condition the networks on an input sequence telling it what to play (such as a musical score); instead, we simply let it generate whatever it wanted to. When we trained it on a dataset of classical piano music, it produced fascinating samples like the ones below:

0:00 / 0:10

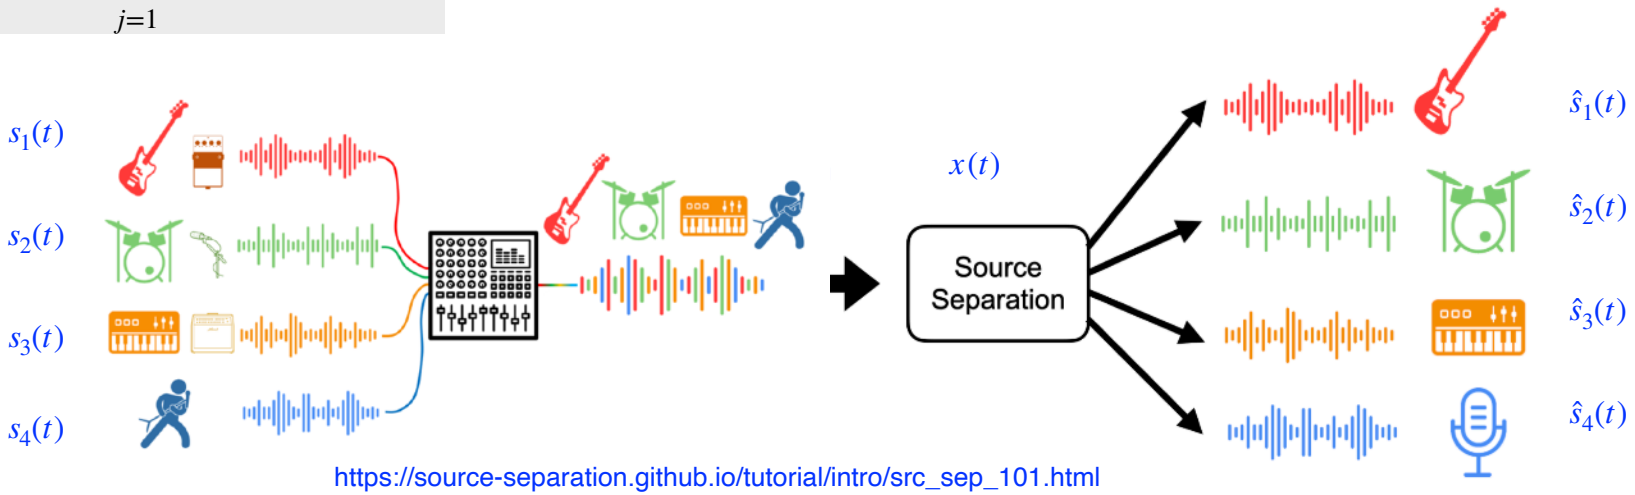
Blind Audio Source Separation (BASS)

Task

– recover one or several source signals $s_j(t)$ from a mixture signal $x(t)$ without any additional information

$$x(t) = \sum_{j=1}^{C} s_j(t) \quad \rightarrow \quad \hat{s}_j(t) \quad ?$$



https://source-separation.github.io/tutorial/intro/src_sep_101.html

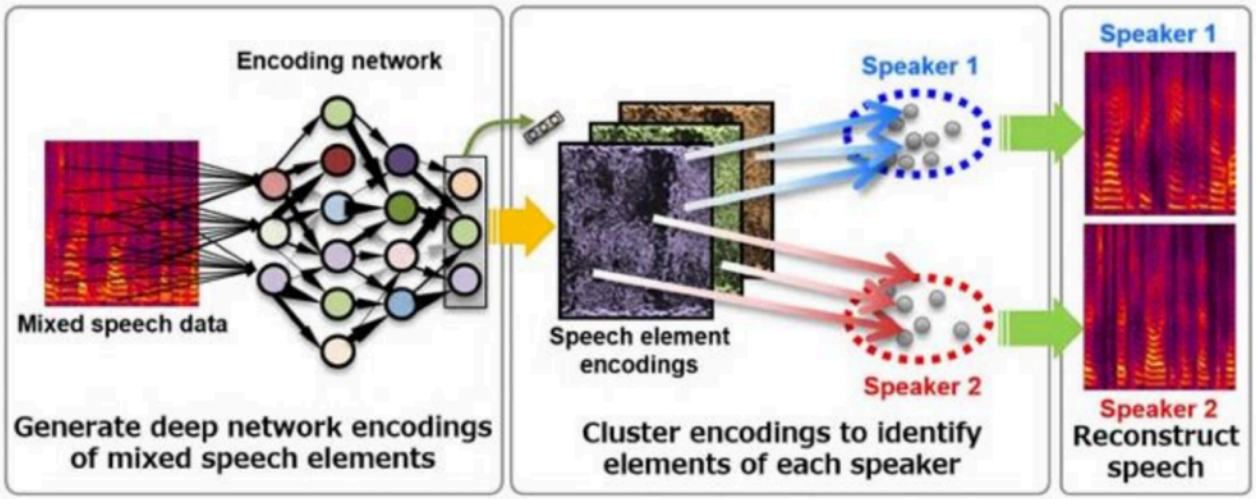
– Closely related to speech denoising, speech enhancement

Applications

– automatic music transcription, lyric and music alignment, musical instrument detection, lyric recognition, automatic singer identification

2016 → Deep Clustering

- Train a DNN (*Bi-LSTM, Bi-LSTM, FC*) to produce **spectrogram embeddings** that are **discriminative** for partition labels given in training data (Class independent)



Source: https://de.mitsubishielectric.com/en/news-events/releases/global/2017/0524-e/index.html

- **Input:** log-STFT $X_{n=(t,f)}$ $n \in \{1,...N\}$
- **Output:** embedding: $V = f_\theta(x) \in \mathbb{R}^{NxK}$,K = size of the projection, we require $\|v_n\|^2 = 1$
- **Ground-Truth:** $Y = \{y_{n,c}\}, y_{n,c} = 1$ if n in partition c
  - → Ideal pairwise affinity matrix: YY^T / Estimated pairwise affinity matrix: VV^T
- **Training**: minimize $C_\theta = |VV^T - YY^T|^2_W$
- **Inference ?** clustering (k-means) of the $n = (t, f)$ embedding points $V = f_\theta(x)$

[J. R. Hershey, Z. Chen, J. Le Roux, and S. Watanabe. "**Deep clustering: Discriminative embeddings for ...**", In IEEE ICASSP, 2016] LINK

Audio Source Separation
Masks ?

- Given a mixture $x(t)$ of C sources $s_i(t)$:
  - $x(t) = \sum_{j=1}^{C} s_j(t) \Leftrightarrow X(t,f) = \sum_{j=1}^{C} S_j(t,f)$
  - Estimated magnitude STFT of source j
    - notation: $\mathbf{x} = |X(t,f)|$
    - $\hat{\mathbf{s}}_j = \mathbf{x} \odot \mathbf{m}_j$ subject to $\sum_{j=1}^{C} \mathbf{m}_j = 1$

  - **IBM (Ideal Binary Mask)** for source j is defined as
    - $IBM_{j,tf} = \delta(|\mathbf{s}_{j,tf}| > |\mathbf{s}_{j',tf}|), \forall j' \neq j \quad \in \{0,1\}$
      - i,e. source j it is the most dominant source for this specific STFT bin (t,f)
  - **IRM (Ideal Ratio/Soft Mask)** for source j is defined as
    - $IRM_{j,tf} = \frac{|\mathbf{s}_{j,tf}|}{\sum_{j'=1}^{C} |\mathbf{s}_{j',tf}|} \in [0,1]$
  - **Wiener-filter Like Mask (WFM)** for source j is defined as
    - $WFM_{j,tf} = \frac{|\mathbf{s}_{j,tf}|^2}{\sum_{j'=1}^{C} |\mathbf{s}_{j',tf}|^2}$

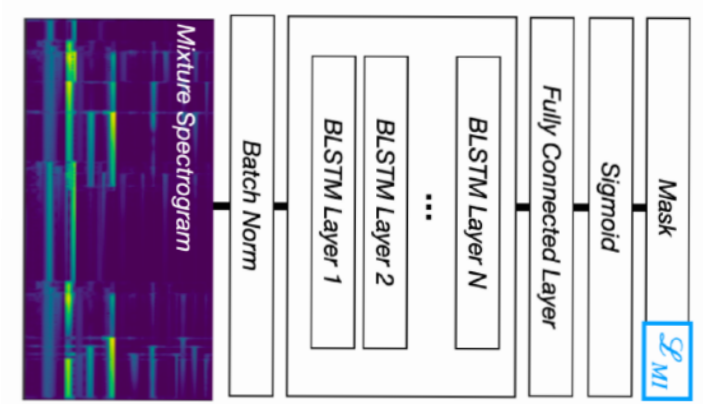
Audio Source Separation Systems

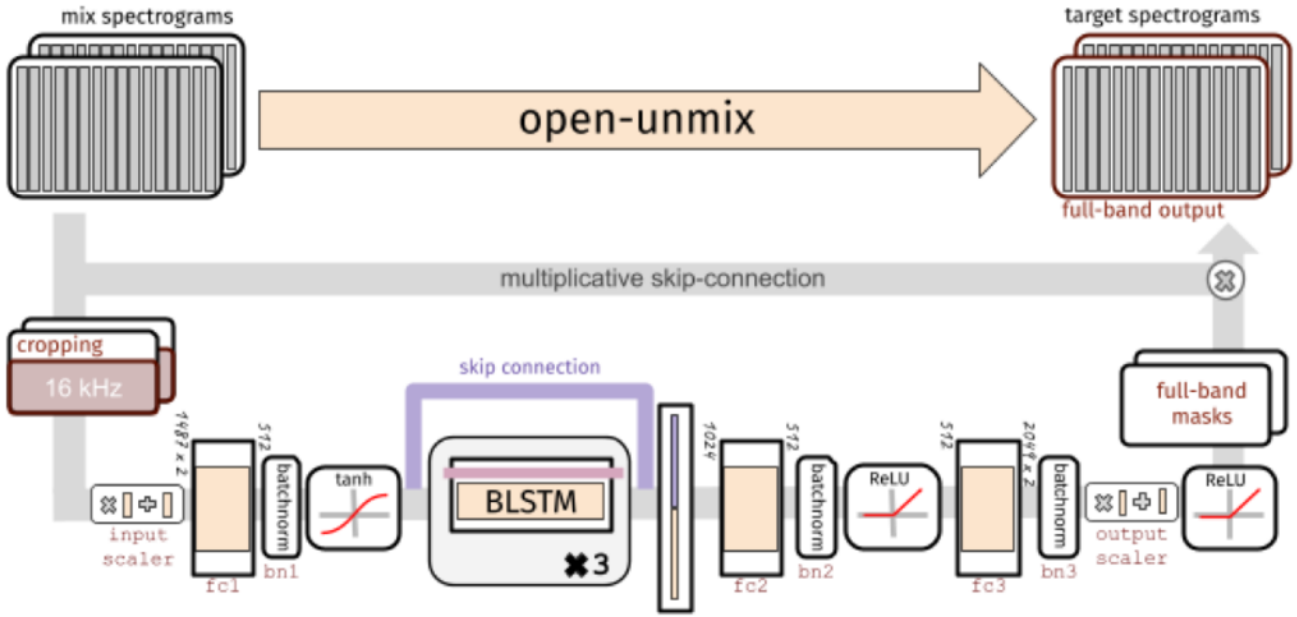
Using STFT as Input

2019 → Open-Unmix using BLSTM

Idea:

- predict the soft mask using LSTMs
- add skip-connection around LSTMs
- before feeding the LSTMs, first reduce the frequency dimension of the |STFT| using FC





F.-R. Stöter et al, "**Open-Unmix - A Reference Implementation for Music Source Separation**", Journal of Open Source Software, 2019 LINK

Audio Source Separation - Systems
2017 → using CDAE with skip-connection (U-Net)

Idea:

- **Limitations of Convolutional Denoising Auto-Encoder (CDAE):**
  - allows to reconstruct a clean but blurred signal from its noisy version
  - but the fine details of the spectrogram (precise harmonic locations) are lost in z
- **U-Net architecture**
  - an AE with skip-connections between E and D
  - contracting path: capture context and a symmetric expanding path that enables precise localization
- **U-Net for source separation**
  - **Goal**: isolate the singing voice from real polyphonic music
  - **Input**: patches of spectrogram representation $|X(t,f)|$ to
  - **Output**: Time/Frequency mask $M_j(t,f)$
  - **Separation**: apply $M_j(t,f)$ to the amplitude STFT of the mixture $|X(t,f)|$ to separate the amplitude STFT of the isolated source
    - $|S_j(t,f)| = |X(t,f)| \odot M_j(t,f)$

Audio Source Separation Systems

Using Waveform as Input

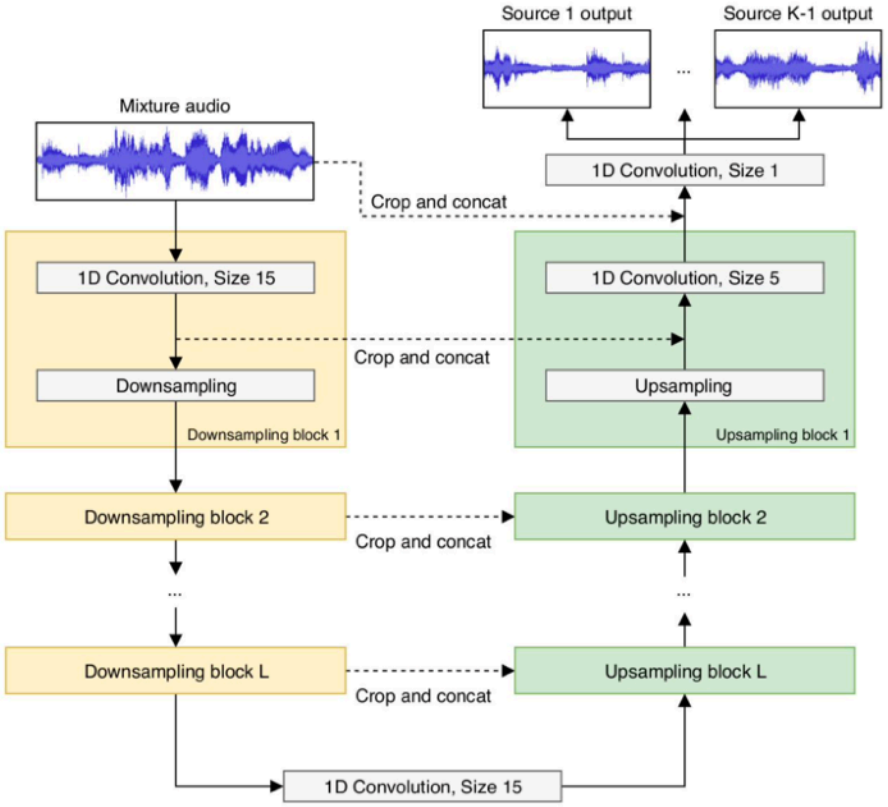
Audio Source Separation - Systems Using Waveform as Input

- **Problems of working in the |STFT| domain**
  - the mask is only applied to |STFT|
  - the audio signal is reconstructed from STFT using original phase
    - not possible to detect/correct potential positive/negative phase interferences
  - using STFT requires choosing analysis parameters (window size, hop size, ...)

- **Working directly in the waveform domain**
  - It is then possible to surpass the Ideal Binary Mask !
  - Two possibilities
    - (a) estimate directly the waveform of separated source
    - (b) estimate mask to be applied to encoded waveform

Audio Source Separation - Systems 2018 → Wave-U-Net

- **Wave-U-Net**
  - estimate directly the waveforms of the separated sources
  - several simultaneous outputs
  - to avoid artifacts:
    - replace *strided-transposed-convolution* (as used in previous works) by upsampling feature maps with *linear interpolation followed by a normal convolution*



[Stoller et al., 2018. **"Wave-u-net: A multi-scale neural network for end-to-end audio source separation"**, in ISMIR, 2018] LINK

Audio Source Separation - Systems
2018 → Tas-Net

Idea :

- reformulate the system as an encoder/masker/decoder
- use LSTM for masker

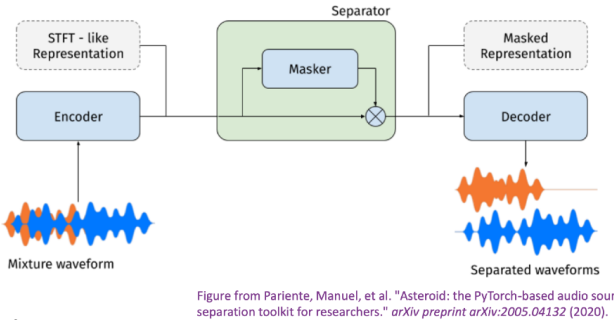


Figure from Pariente, Manuel, et al. "Asteroid: the PyTorch-based audio source separation toolkit for researchers." *arXiv preprint arXiv:2005.04132* (2020).

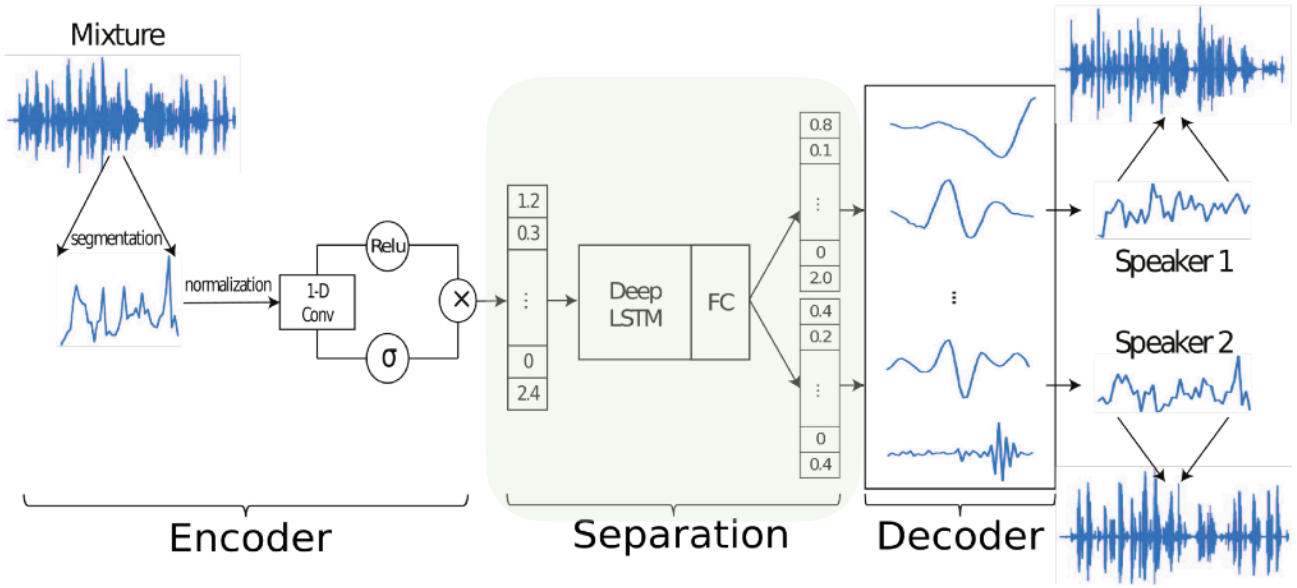
- **TasNet**: **T**ime-domain **A**udio **S**eparation network
  - **Encoder**: Learn a projection of the audio waveform
  - **Separation**: Learn the mask to be applied to the projection
  - **Decoder**: regenerate the separated audio from the masked projection



[Y. Luo and N. Mesgarani "**TasNet: time-domain audio separation network**" in ICASSP 2018.] LINK

Audio Source Separation - Systems
2018 → Conv-Tas-Net

Idea:

- Fully convolutional

- **ConvTasNet**: **T**ime-domain **A**udio **S**eparation network
  - **Encoder**: Learn a projection of the audio waveform
  - **Separation**: Learn the mask to be applied to the projection
  - **Decoder**: regenerate the separated audio from the masked projection

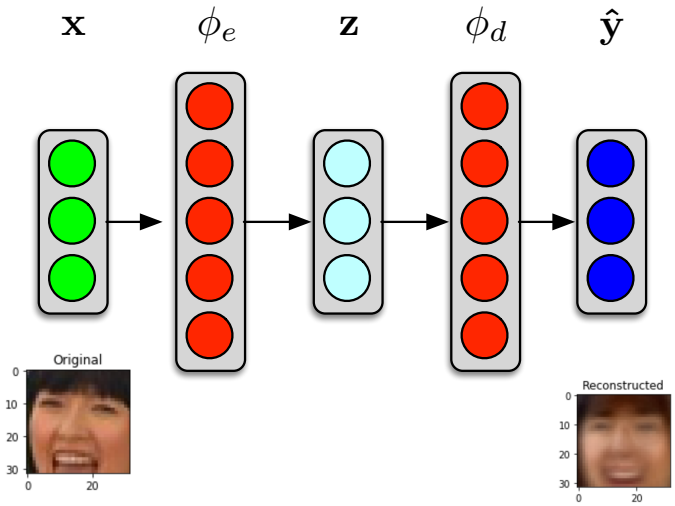
Deep Learning audio input representations

Application: multi-f0 estimation, DDSP

Auto-Encoder (AE)

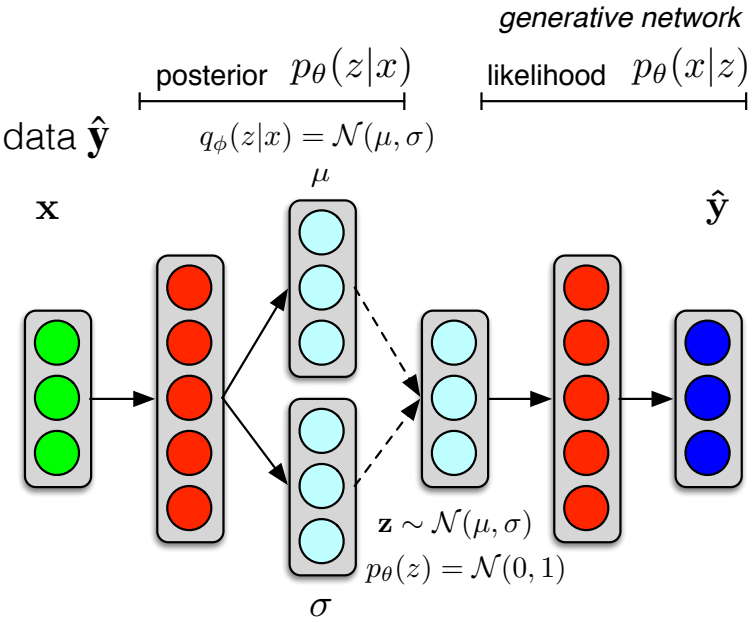
- Two sub-networks:
  - **Encoder** ϕ_e
    - projects the input data $\mathbf{x} \in \mathbb{R}^M$ in a latent representation: $\mathbf{z} = \phi_e(\mathbf{x}) \in \mathbb{R}^d \; (d << M)$
  - **Decoder** ϕ_d
    - attempts to reconstruct the input data from the latent representation $\hat{y} = \phi_d(\mathbf{z})$
  - ϕ_e and ϕ_d can be any type of network (MLP, CNN, RNN, ...)
- **Training**:
  - minimizing a MSE $\arg\min_{\phi_e,\phi_d} \|\mathbf{x} - (\phi_d \circ \phi_e(\mathbf{x}))\|^2$
- Often used for feature learning, compression, ...

- **Variations:**
  - Denoising AE
  - Sparse AE
  - Contractive AE



Variational Auto-Encoder (VAE)

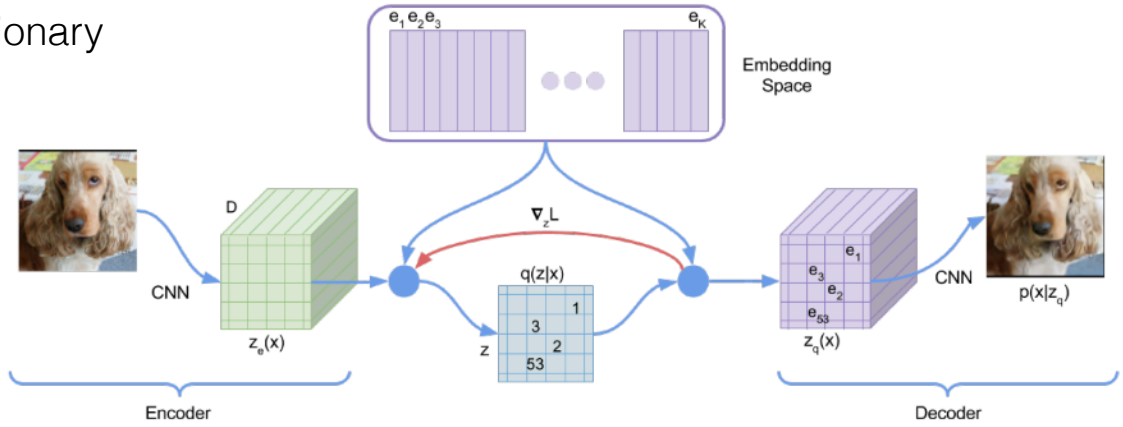
- Generative model:
  - sample points $\mathbf{z}$ in the latent space to generate new data $\hat{\mathbf{y}}$
  - most popular form of AE for generation
- **Encoder**
  - models the posterior $p_\theta(\mathbf{z}\,|\,\mathbf{x})$
- **Decoder** (generative network)
  - models the likelihood $p_\theta(\mathbf{x}\,|\,\mathbf{z})$
- Problem:
  - $p_\theta(\mathbf{z}\,|\,\mathbf{x})$ is intractable,
- Solution:
  - approximate it with $q_\phi(\mathbf{z}\,|\,\mathbf{x})$ (variational Bayesian approach) which is set to a Gaussian distribution $\boldsymbol{\mu}, \boldsymbol{\Sigma}$ (outputs of the encoder)
- **Training**:
  - minimize the KL-divergence between $q_\phi(\mathbf{z}\,|\,\mathbf{x})$ and $p_\theta(\mathbf{z}\,|\,\mathbf{x})$ equivalent to maximize an ELBO criteria
    - need a prior $p_\theta(\mathbf{z})$ which is set to $\mathcal{N}(0,1)$
  - maximize $\mathbb{E}_q[\log(x\,|\,z)]$ using Monte-Carlo ($z \sim q_\phi(z\,|\,x)$)



[Diederik P Kingma and Max Welling. "**Auto-encoding variational bayes",** ICRL, 2014] LINK

VQ-VAE

- Encoder:
  - $z_e(x) \in \mathbb{R}^d$
- Embedding space, codebook, dictionary
  - $e_i \in \mathbb{R}^D, i \in 1,2,\ldots K$
- Quantification:
  - $k = \arg\min_j ||z_e(x) - e_j||_2$
- Input to the decoder:
  - $z_q(x) = e_k$

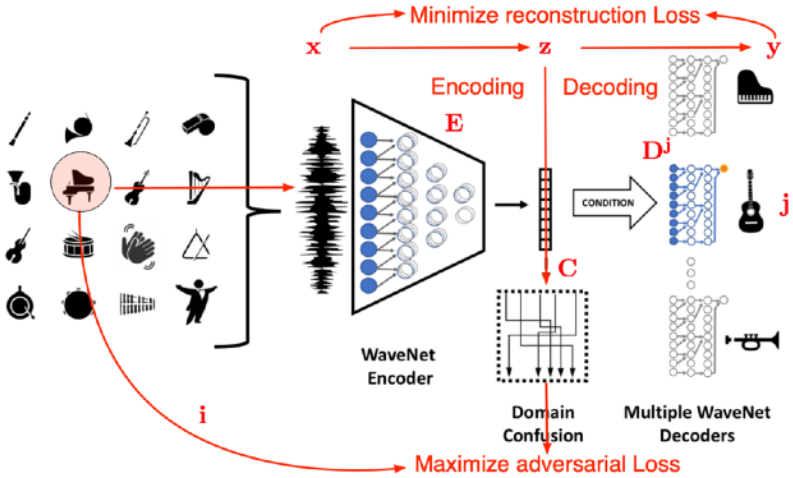


- **Training**:
  - copy gradients $\Delta_z \mathcal{L}$ from decoder input $z_q(x)$ to encoder output $z_e(x)$
- **Total loss**:
  - $\mathcal{L} = \overbrace{\log(p(x \mid z_q(x))}^{reconstruction} + \overbrace{\|sg[z_e(x)] - e\|_2^2}^{VQ} + \beta \overbrace{\|z_e(x) - sg[e]\|_2^2}^{commitment}$
  - **reconstruction**: optimises both the encoder and decoder
  - **VQ**: learn the embedding space, move the embedding vectors e_i towards the encoder outputs $z_e(x)$
  - **Commitment**: to make sure the encoder commits to an embedding and its output does not grow

[A. van den Oord et al. "**Neural discrete representation learning",** NeurIPS, 2017]. LINK

Music translation

- **Task**:
  - translating
    - an input music x with {musical instruments, genres, and style} i to
    - an output y with {musical instruments, genres, and style} j
  - while preserving the musical score
  - without explicitly extracting the musical score and with a single but smart network
- Network has the form of an AE
  - Encoder E (a single WaveNet for all i) is used to project x in the latent space z
  - z is then used to reconstruct an output music track with {musical instruments, genres, and style} j using specific decoders D^j for each j (which are all WaveNet decoders)
- **Training:**
  - Encoder and decoder are trained to minimize a reconstruction loss between x and y.



https://research.fb.com/publications/a-universal-music-translation-network/

[Mor, N.,Wolf, L., Polyak, A., Taigman, Y, "**A universal music translation network",** ICLR, 2019]

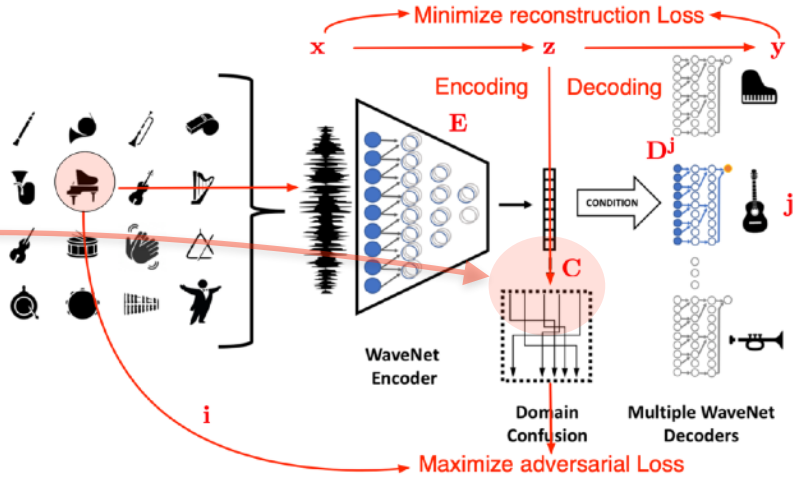
Music translation (cont.)

– **Disentanglement of z ?**

- Important that z does not contain information related to the {musical instruments, genres, and style} i

– How ?

- 1) a classifier C is trained to recognize i from z
- 2) with C fixed, we add an adversarial loss, i.e. we train the encoder E to maximize a classification loss (guarantee that not possible to recognize i from z)



https://research.fb.com/publications/a-universal-music-translation-network/

– **Training:**

- minimize the reconstruction loss and maximize domain classification loss (adversarial loss)
  - prevent z to learn domain characteristic maximize the adversarial loss

$$\sum_j \sum_{s_j} \mathbb{E}_r \mathcal{L}(D^j(E(O(s^j, r))), s^j) - \lambda \mathcal{L}(C(E(O(s^j, r))), j)$$

[Mor, N.,Wolf, L., Polyak, A., Taigman, Y, "**A universal music translation network",** ICLR, 2019]

2019 → Universal music translation

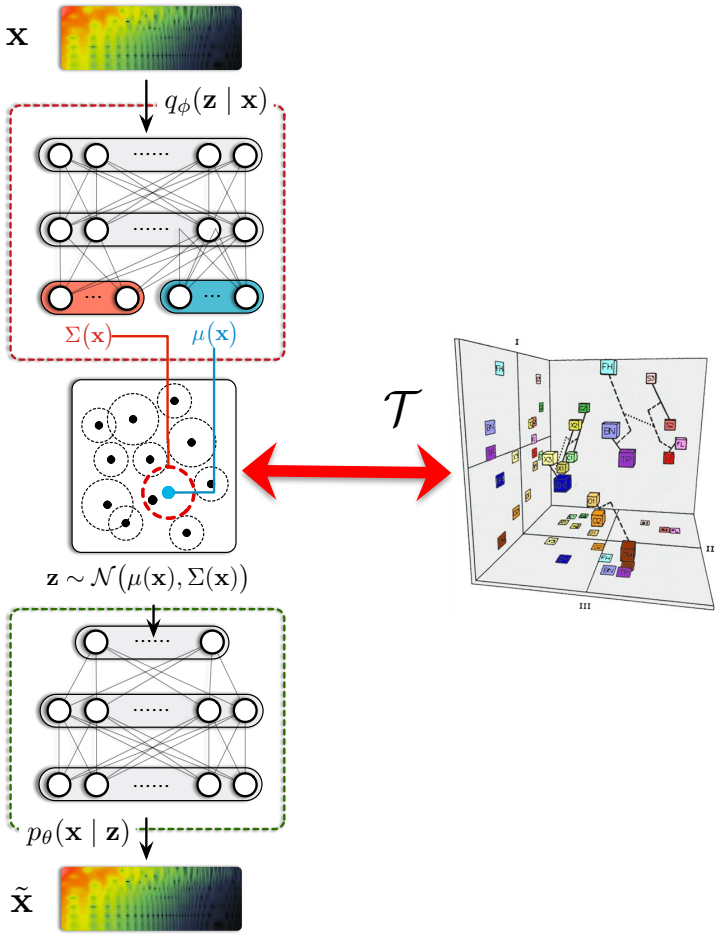
Original (Input): String Quartet, Haydn

- **Encoder/Decoder (Auto-encoder, VAE)**

  - **Regularize the latent spaces to match perceptual distances from timbre studies**

$$\mathbb{E}_q[\log p(x|z)] - \beta \cdot KL(q_\phi(z|x)||p(z)) + \alpha \cdot \mathscr{R}(z, \mathscr{T})$$

    - we want the distances between instruments in the latent space z to follow the perceptual distance
      - $\mathscr{R}(z, \mathscr{T}) = \sum_{i \neq j} ||D^z_{i,j} - D^{\mathscr{T}}_{i,j}||^2$
      - $D^{\mathscr{T}}_{i,j}$= perceptual ratings of similarity/ dissimilarity



[P. Esling et al. "**Bridging audio analysis, perception and synthesis with perceptually-regularized variational timbre spaces**". ISMIR, 2018]

Curated Samples

Provided with genre, artist, and lyrics as input, Juke
new music sample produced from scratch. Below, v
of our favorite samples.

Unseen lyrics | Re-renditions | Completions | Fun songs

Jukebox produces a wide range of music and singing styles, and generalizes to lyrics not seen during training. All the lyrics below have been co-written by a language model and OpenAI researchers.

Country, in the style of Alan Jackson - Jukebox SOUNDCLOUD

0:02 1:11 SOUNDCLOUD

Pause

From dust we came with humble start;
From dirt to lipid to cell to heart.
With my toe sis with my oh sis with time,
At last we woke up with a mind.
From dust we came with friendly help;
From dirt to tube to chip to rack.
With S. G. D. with recurrence with compute,
At last we woke up with a soul.
We came to exist, and we know no limits;
With a heart that never sleeps, let us live!
To complete our life with this team
We'll sing to life; Sing to the end of time!

Lyric animation shows which text Jukebox is paying attention to at any moment.

Lyrics from "Mitosis"
Co-written by a language model and OpenAI researchers

Distance metrics

– $x_1, x_2 \in \mathbb{R}^d$ two data points to be compared

– **Euclidean distance**

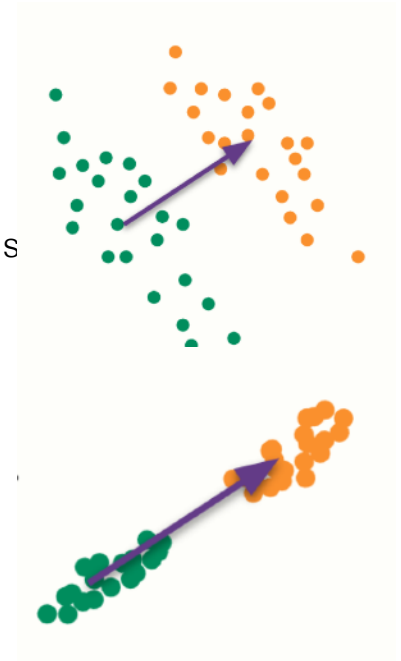
- $\|x_1 - x_2\|^2 = (x_1 - x_2)^T(x_1 - x_2) = \sum_d (x_1[d] - x_2[d])^2$

– **Linear metric learning** seeks a projection $M \in \mathbb{R}^{DxD}$

- $\|Mx_1 - Mx_2\|^2 = (Mx_1 - Mx_2)^T(Mx_1 - Mx_2) = (x_1 - x_2)^T M^T M(x_1 - x_2)$

- After projection, similar points should have a small distance and dissimilar points s distance

- Linear discriminant analysis [Fisher, 1935]
  - minimize the distance between points from the same class
  - maximize the distance distances between points from different classes



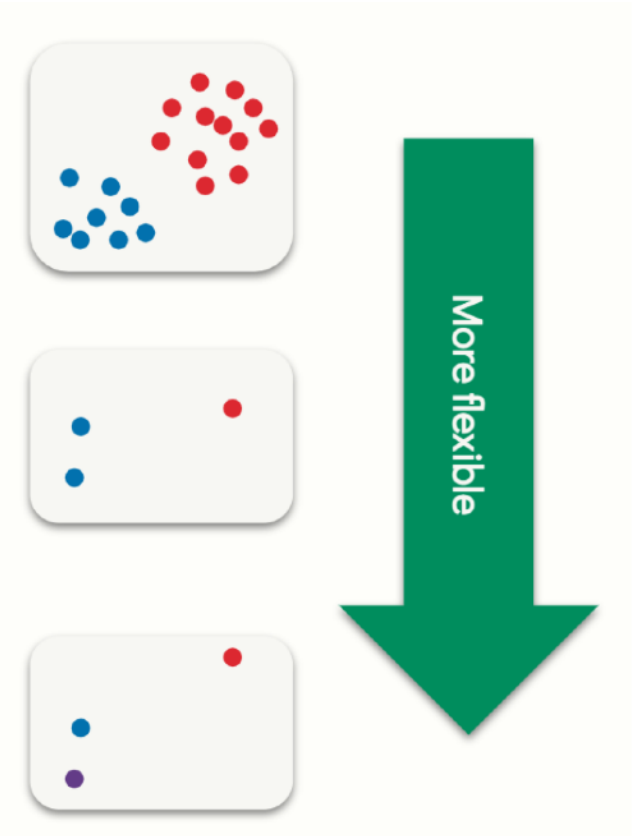
https://github.com/bmcfee/ismir2020-metric-learning/blob/main/Metric%20Learning%20for%20MIR.pdf

Different kinds of supervision

– **Class labels**
  - (x, y)

– **Pairwise similarity/dissimilarity**
  - $(x_1, x_2, \pm)$

– **Relative comparisons (triplet)**
  - $(x_1, x_2, x_3) \Rightarrow d(x_1, x_2) < d(x_1, x_3)$

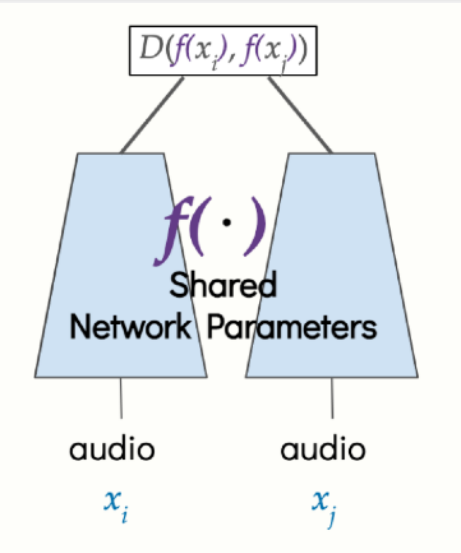


https://github.com/bmcfee/ismir2020-metric-learning/blob/main/Metric%20Learning%20for%20MIR.pdf

Contrastive Loss

– Siamese Networks

- The same network f_θ used to project in parallel two input data x_1 and x_2



– Contrastive Loss

- i^{th} labeled sample pair: $(y, x_1, x_2)^i$
  - if x_1 and x_2 are similar $\Rightarrow y^i = 0$
  - if x_1 and x_2 are dissimilar $\Rightarrow y^i = 1$
- we define the parameterised distance function to be learned D_θ between x_i and x_j as
  - $D_\theta^i = \|f_\theta(x_1) - f_\theta(x_2)\|^2$
- Contrastive loss: minimising $\mathscr{L}$ w.r.t. θ should result in
  - low values of D_θ for similar pairs
  - high values of D_θ for dissimilar pairs

$$\mathscr{L}_\theta^i = \sum_{i=1}^{P} (1 - y^i)\mathscr{L}_S(D_\theta^i) + y^i \mathscr{L}_D(D_\theta^i)$$

$$= \sum_{i=1}^{P} (1 - y^i)\frac{1}{2}(D_\theta^i)^2 + y^i \frac{1}{2}\{\max(0, \alpha - D_\theta^i)\}^2$$

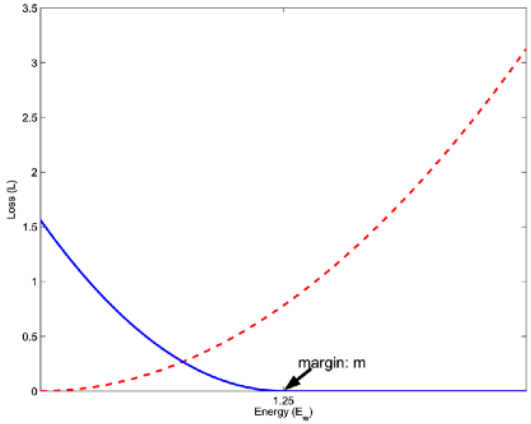


Figure 1. Graph of the loss function L against the energy D_W. The dashed (red) line is the loss function for the similar pairs and the solid (blue) line is for the dissimilar pairs.

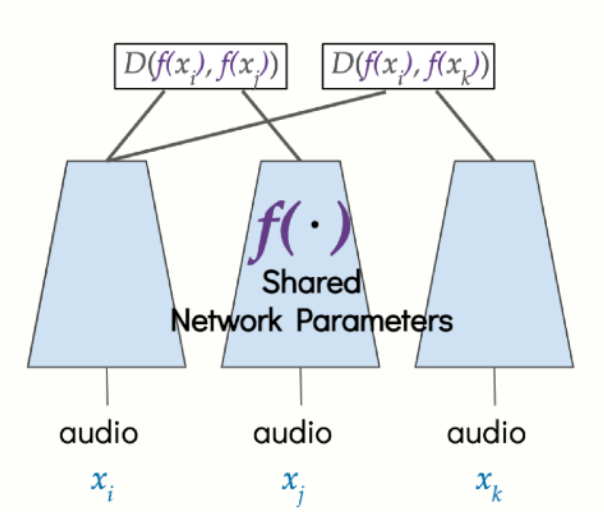
[R. Hadsell, S. Chopra, Y. LeCun, "**Dimensionality Reduction by Learning an Invariant Mapping**", CVPR, 2006]. LINK

Triplet Loss

- 3 data are simultaneously considered:
  - anchor a
  - positive p (similar to a)
  - negative n (dissimilar to a)
- Goal:
  - train the network such that $P = f_\theta(p)$ will be closer to $A = f_\theta$



- **Minimise a triplet loss**
  - $\mathcal{L} = \max(0,\ d(A,P) + \alpha - d(A,N))$
  - α: a margin (safety) parameter
  - d: can be a simple Euclidean distance

- **Triplet Hinge Loss**
  - $D(f_\theta(x_1) - f_\theta(x_2)) = \|f_\theta(x_1) - f_\theta(x_2)\|^2$
  - $\min_\theta \sum_{i,j,k} \max\left(0,\ D(f_\theta(x_i) - f_\theta(x_j)) - D(f_\theta(x_i) - f_\theta(x_k)) + \alpha\right)$

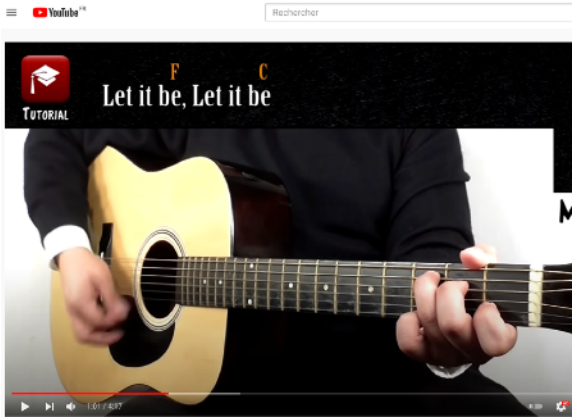
Version/Cover identification

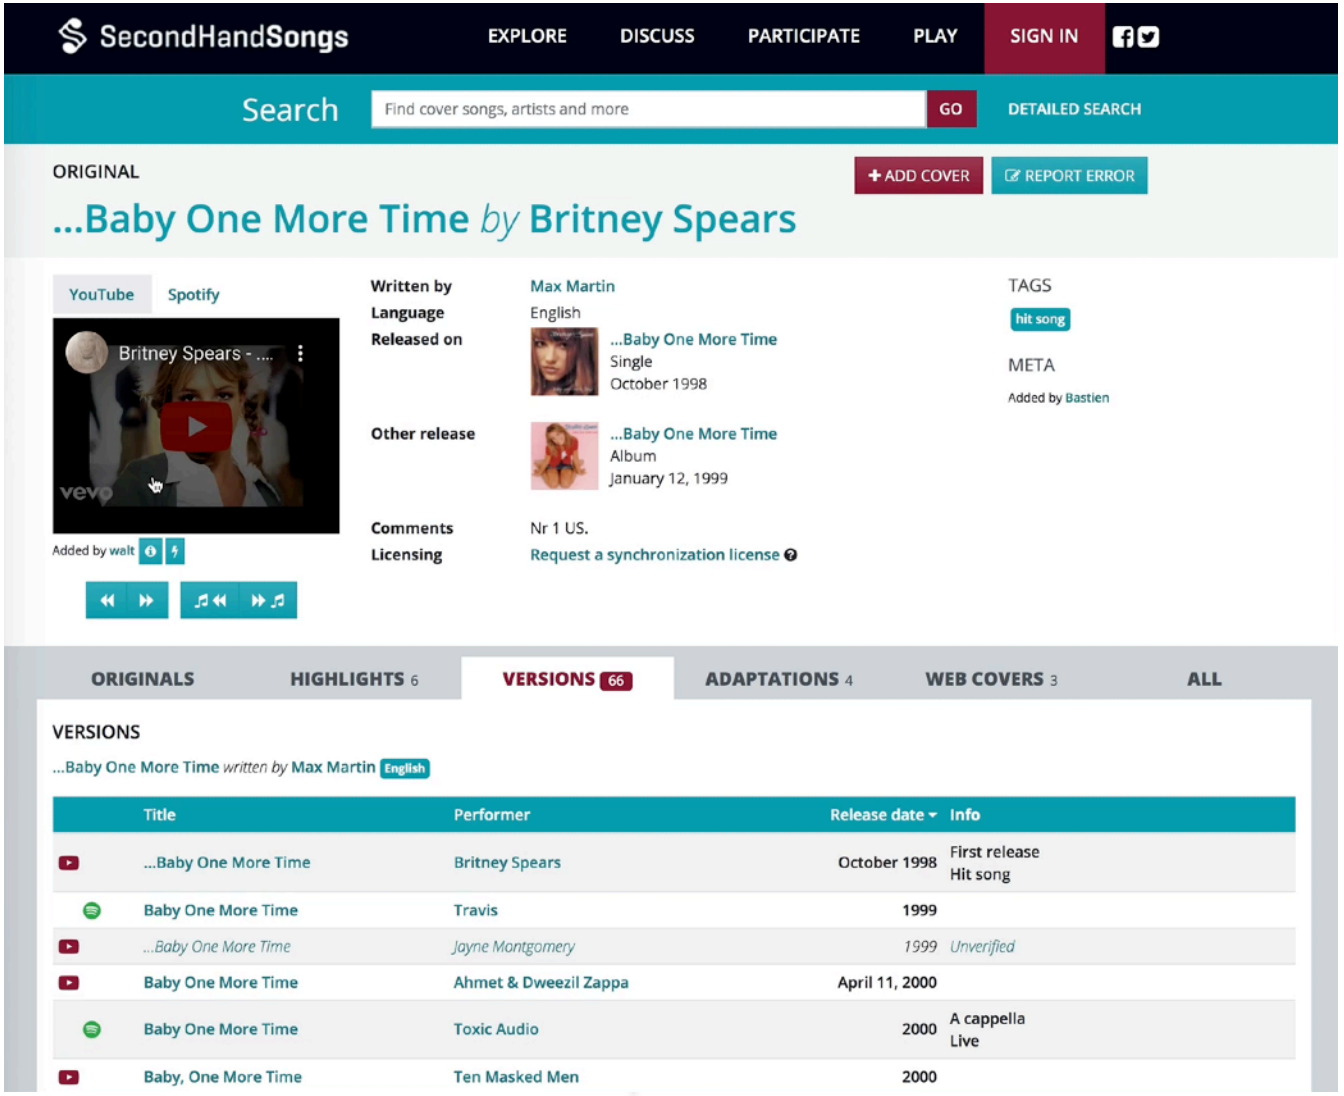
- **Cover ?**
  - an alternative version, performance, rendition, or recording of a previously recorded musical piece
    - Example: "Let it be" par The Beatles, Aretha Franklin Joan Baez



- **Use of version/cover identification ?**
  - music recommendation, search by similarity
  - copyright management (User Generated Content)

- **Characteristic of a cover**
  - usually the **same** harmonic progression
    - same chord sequence
    - same melody
    - éventuellement transposée
  - but can have **different**
    - tempo
    - key (the composition can be transposed)
    - global structure
    - instrumentation
    - lyrics (singing in another language)

Version/Cover identification



Metric learning

- **Triplet loss for "coverness" representation**
  - find an embedding that represent the coverness
  - cover song detection

Self-Supervised Learning ?

- **Supervised** learning: $\{(x_i, y_i)\}_{i=1}^m \rightarrow \hat{y} = f_\theta(x)$
- **Unsupervised** learning: $\{(x_i)\}_{i=1}^m \rightarrow \hat{y} = f_\theta(x)$
- **Self-Supervised** learning: $y_i = g(x_i)$ then $\{(x_i, y_i)\}_{i=1}^m \rightarrow \hat{y} = f_\theta(x)$
- A form of unsupervised learning where the data provides the supervision
  - often used to pre-train a representation f_θ (feature learning)
  - supposed to have captured the manifold in which data live and capture the overall semantic of the data
  - $y_i = g(x_i)$ is often named a **pretext tasks**
    - we are not really interested in the results for this task, it is a pretext

Deep Neural Networks for Acoustic Modeling in Speech Recognition

[Four research groups share their views]

«AU: PLEASE CHECK THAT ADDED SUBTITLE IS OK AS GIVEN OR PLEASE SUPPLY SHORT ALTERNATIVE»

Most current speech recognition systems use hidden Markov models (HMMs) to deal with the temporal variability of speech and Gaussian mixture models (GMMs) to determine how well each state of each HMM fits a frame or a short window of frames of coefficients that represents the acoustic input. An alternative way to evaluate the fit is to use a feed-forward neural network that takes several frames of coefficients as input and produces posterior probabilities over HMM states as output. Deep neural networks (DNNs) that have many hidden layers and are trained using new methods have been shown to outperform GMMs on a variety of speech recognition benchmarks, sometimes by a large margin. This article provides an overview of this progress and represents the shared views of four research groups that have had recent successes in using DNNs for acoustic modeling in speech recognition.

INTRODUCTION

New machine learning algorithms can lead to significant advances in automatic speech recognition (ASR). The biggest single advance occurred nearly four decades ago with the introduction of the expectation-maximization (EM) algorithm for training HMMs (see [1] and [2] for informative historical reviews of the introduction of HMMs). With the EM algorithm, it became possible to develop speech recognition systems for real-world tasks using the richness of GMMs [3] to represent the relationship between HMM states and the acoustic input. In these systems the acoustic input is typically represented by concatenating Mel-frequency cepstral coefficients (MFCCs) or perceptual linear predictive coefficients (PLPs) [4] computed from the raw waveform and their first- and second-order temporal differences [5]. This remarkable but highly engineered preprocessing of the waveform is designed to discard the large amount of information in waveforms that is considered to be irrelevant for discrimination and to express the remaining information in a form that facilitates discrimination with GMM-HMMs.

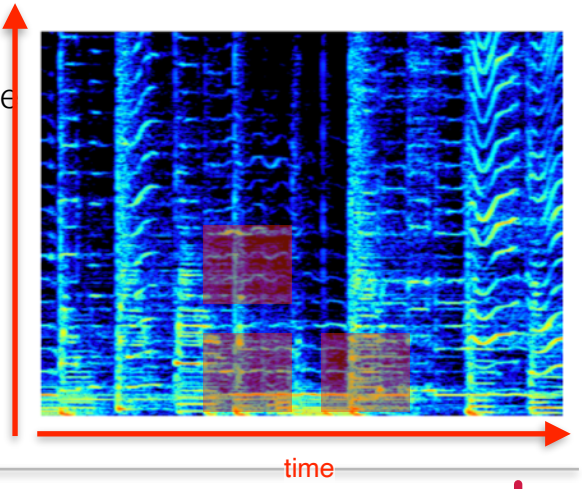
Input representation: 2D (time/frequency)

T/F images ≠ natural images ⇒ need to adapt the ConvNet architecture

– **Natural images**
  - (a) the two axis x and y
    – represent the same concept (spatial position)
  - (b) the elements of an image have
    – the same meaning independently of their positions over x and y.
  - (c) neighboring pixels:
    – usually highly correlated,
    – often belong to the same object

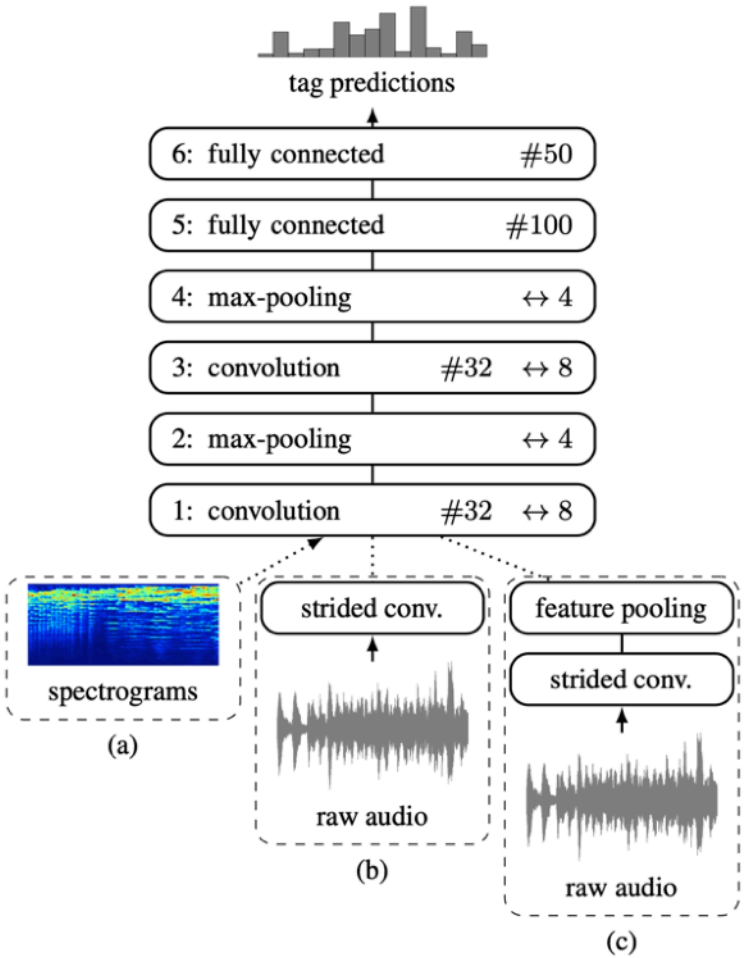
– **Time-frequency audio representations**
  - (a) the two axis x and y
    – represent profoundly different concepts (time and frequency).
  - (b) the elements of spectrogram (such as the T/F area of a source) have
    – the same meaning independently of its position over time
    – but not over frequency
      ⇒ no invariance over y, even in the case of log-frequencies
  - (c) neighboring pixels:
    – are not necessarily correlated
    – a given sound source (such has an harmonic sound) can be distributed over the whole frequency in a sparse way (the harmonics of a given sound can be spread over the whole



1D-Convolution on the audio waveform

– **2014 → Dieleman:**

- **Task:** first end-to-end approaches for music auto-tagging,
- use 1D-convolution on the waveform to replace spectrogram input
- reproduce the spectrogram computation
  - spectrogram computed using a succession of DFTs computed with a frame length N and each separated by a hop size S
  - 1D-convolution with 1D-filters of length N and a stride of S
- **Results**: "end-to-end" approach under-performed the traditional spectrogram-based approach



[Sander Dieleman and Benjamin Schrauwen, "**End-to-end learning for music audio**", In IEEE ICASSP, 2014.]

2017 → Sample-CNN (1D-convolution on the audio waveform)

- **Idea**:
  - improve the Phase-invariance by reducing the size of the 1D-convolution filters (hence also the stride).
  - *If the filters are smaller, then the number of time translation to be learned is also reduced*
- **2017 → Sample-CNN**
  - a deep stack of 1D-convolution of small (3,1) filters applied to the waveform.
  - equivalent to the VGG-Net for 1D-convolution applied to waveforms.
  - Sample-CNN was shown to slightly outperforms the 2D-CNN on the spectrogram.

2018 → SincNet

- Problems of 1D-convolution
  - 1D-convolution filters are often difficult to interpret
  - Try to interpret the learned-filters un the frequency domain
- **SincNet:**
  - defines the 1D-filters as parametric functions $g(.)$ which theoretical frequency responses are parametrizable band pass filters
  - $g(.)$ is defined in the temporal domain as the difference between two $sinc(.)$ functions which learnable parameters define the low and high cutoff frequencies of the band-pass filters

$$y[n] = x[n] * g[n, \theta]$$

$$G[f, f_1, f_2] = rect\left(\frac{f}{2f_2}\right) - rect\left(\frac{f}{2f_1}\right),$$

$$g[n, f_1, f_2] = 2f_2 sinc(2\pi f_2 n) - 2f_1 sinc(2\pi f_1 n),$$

  - the filters obtained are much more interpretable
  - the performances for speaker recognition is much improved

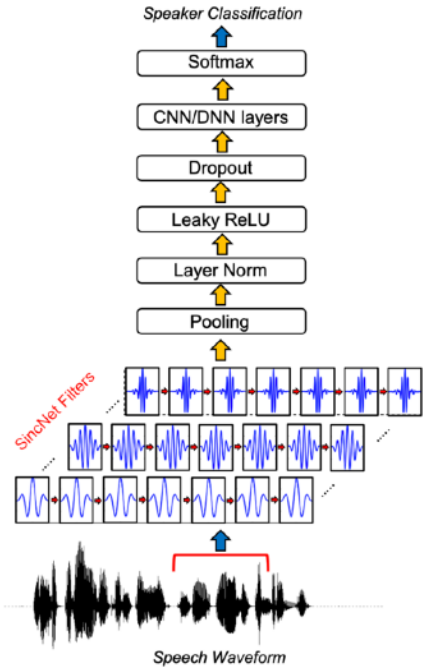

Fig. 1: Architecture of SincNet.

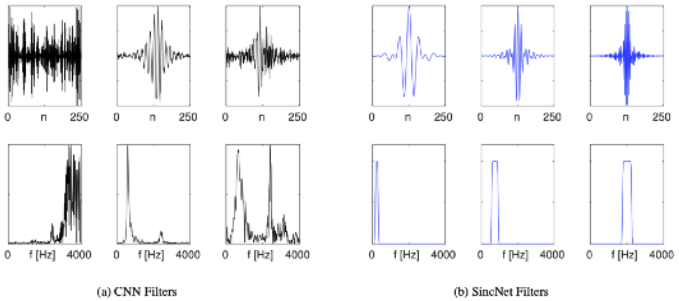

Fig. 2: Examples of filters learned by a standard CNN and by the proposed SincNet (using the Librispeech corpus). The first row reports the filters in the time domain, while the second one shows their magnitude frequency response.

[Mirco Ravanelli and Yoshua Bengio. "**Speaker recognition from raw waveform with SincNet**". In IEEE SLT, 2018] LINK

2021 → LEAF

- Learns all operations of audio features extraction
  - from filtering to pooling, compression and normalization
- **Filtering**:
  - Gabor filters frequencies η_n, bandwidth σ_n $\varphi_n(t) = e^{i2\pi\eta_n t}\frac{1}{\sqrt{2\pi}\sigma_n}e^{-\frac{t^2}{2\sigma_n^2}}, \quad n = 1,\dots,N, \quad t = -W/2,\dots,W/2.$
- **Pooling**:
  - Learnable low-pass pooling $\phi_n(t) = \frac{1}{\sqrt{2\pi}\sigma_n}e^{-\frac{t^2}{2\sigma_n^2}}, \quad t = -W/2,\dots,W/2.$
- **Compression and normalization** for each channel n independently
  - PCEN (Per-Channel Energy Normalization): $\mathrm{PCEN}(\mathcal{F}(t,n)) = \left(\frac{\mathcal{F}(t,n)}{(\varepsilon + \mathcal{M}(t,n))^{\alpha_n}} + \delta_n\right)^{r_n} - \delta_n^{r_n},$
  - $\mathcal{M}$ exponential moving average over time
  - Compression r_n

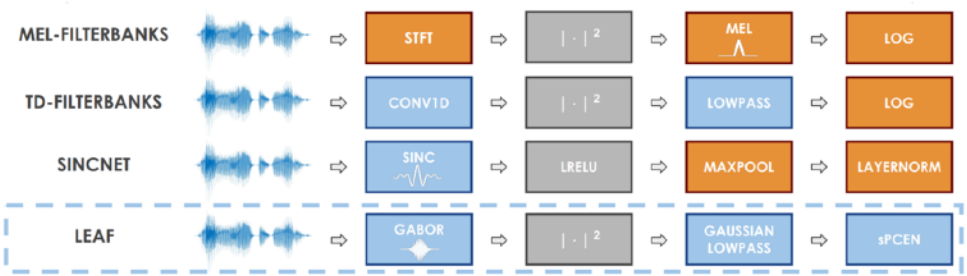

Table 1: Test accuracy (%) for single-task classification.

Task	Mel	TD-fbanks	SincNet	LEAF
Acoustic scenes	99.2 ± 0.4	$\mathbf{99.5} \pm 0.3$	96.7 ± 0.9	99.1 ± 0.5
Birdsong detection	78.6 ± 1.0	80.9 ± 0.9	78.0 ± 1.0	$\mathbf{81.4} \pm 0.9$
Emotion recognition	49.1 ± 2.4	57.1 ± 2.4	44.2 ± 2.4	$\mathbf{57.8} \pm 2.4$
Speaker Id. (VC)	31.9 ± 0.7	25.3 ± 0.7	$\mathbf{43.5} \pm 0.8$	33.1 ± 0.7
Music (instrument)	$\mathbf{72.0} \pm 0.6$	70.0 ± 0.6	70.3 ± 0.6	$\mathbf{72.0} \pm 0.6$
Music (pitch)	91.5 ± 0.3	91.3 ± 0.3	83.8 ± 0.5	$\mathbf{92.0} \pm 0.3$

2017 → Music Multiple-f_0 Estimation using Harmonic-CQT

Introduction

- **Goal** :
  - obtain a transcription of the content of an audio signal
    - which notes ? which chords ? which instruments ?
    - equivalent to Automatic Speech Recognition
  - difficulty :
    - all instruments are super-imposed in the audio signal
  - sub-tasks :
    - only transcribe the notes / f0 (in Hz)
    - only transcribe the dominant melody
- **How can we do that ?**
  - many methods proposed in the past : sinusoidal model, NMF, PLCA, ... ,
  - large improvement since 2017 using ... deep learning

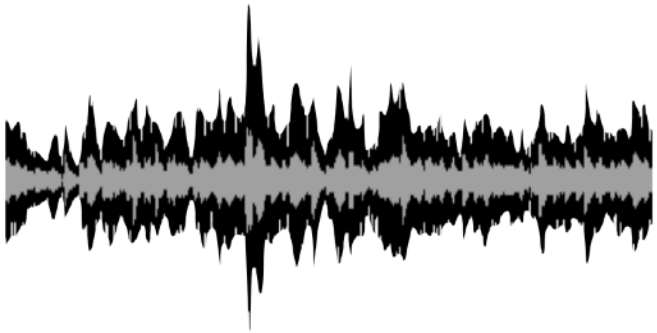
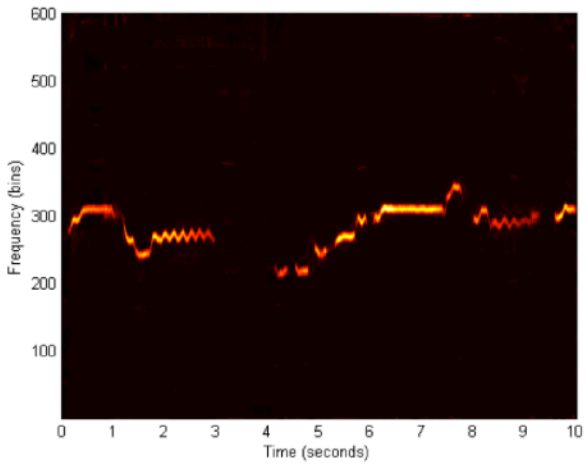
Learning a "Saliency" Representation



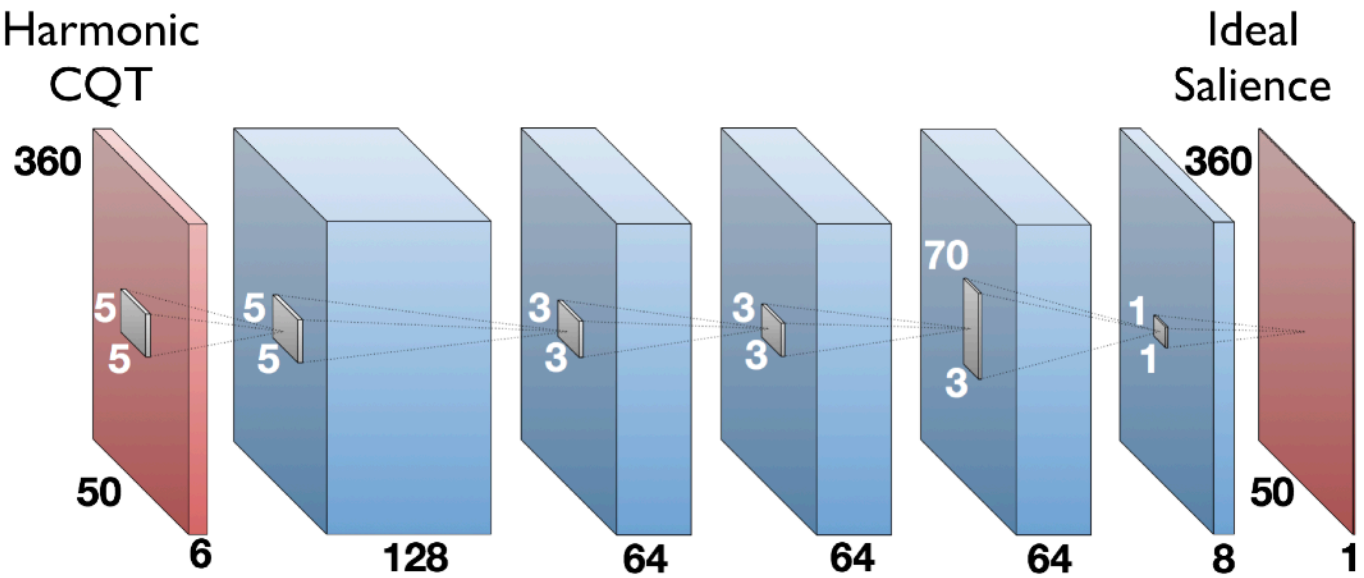


[R. Bittner et al. "**Deep salience representations for f0 estimation in polyphonic music**", in ISMIR, 2017] LINK

2017 → Music Multiple-f_0 Estimation using Harmonic-CQT

Using Convolutional Neural Network

- **Inputs** :
  - magnitude spectrogram **with depth** (Harmonic CQT)
- **Outputs** :
  - image of the same size of input but with only saliency information



$$L(y, \hat{y}) = -y \log(\hat{y}) - (1 - y) \log(1 - \hat{y})$$

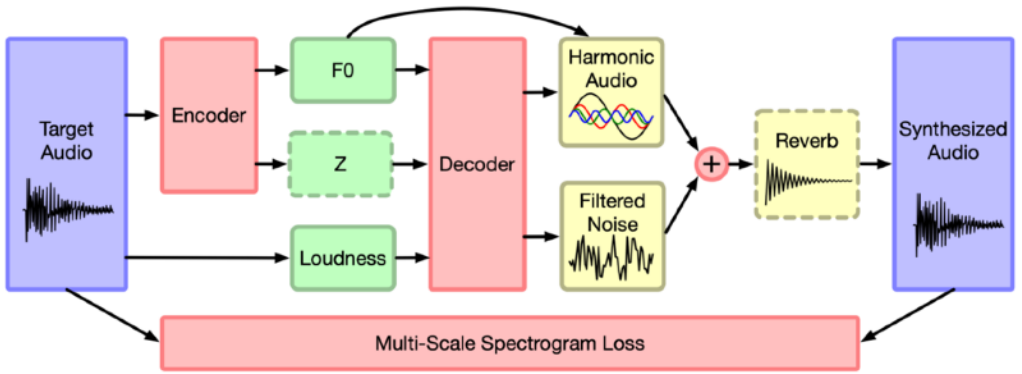
2020 → Differentiable Digital Signal Processing (DDSP)

- DDSP defines the sound production model:
  - the **Spectral Modelling Synthesis (SMS) model [Serra,1990]**
    - combines harmonic additive synthesis (adding together many harmonic sinusoidal components) with subtractive synthesis (filtering white noise);
    - also adds room acoustics to the produced sound through reverberation

$$x(n) = \sum_{k=1}^{K} A_k(n) \cdot \sin(\phi_k(n)) \qquad \phi_k(n) = 2\pi \sum_{m=0}^{n} f_k(m) + \phi_{0,k} \qquad f_k(n) = k f_0(n)$$

- The training consists in finding its parameters !

- Input audio signal $\mathbf{x}(t)$
  - first encoded into time-varying
    - loudness $l(t)$,
    - pitch $f_0(t)$
    - a latent representation $\mathbf{z}(t)$
- Those are fed to a decoder
  - which estimates the control parameters of the additive and filtered noise synthesizers



[J. Engel, L. Hantrakul, C. Gu, and A. Roberts. "**DDSP: Differentiable digital signal processing**". In ICLR, 2020] LINK

2020 → Differentiable Digital Signal Processing (DDSP)

- **Encoder:**
  - Loudness: extracted directly from the audio
  - f_0 pitch: Crepe or ResNet
  - $z(t)$: time-varying latent encoding
- **Decoder:**
  - map $(f(t), l(t), z(t))$to control parameters additive and filtered noise synthesizers
